

Second order stationary p.p.

$$dN(t) = \int \exp\{i\lambda t\} dZ_N(\lambda) dt \quad \text{Kolmogorov}$$

$$N(t) =$$

Power spectrum

$$\text{cov}\{dZ_N(\lambda), dZ_N(\mu)\} = \delta(\lambda - \mu) f_{NN} d\lambda d\mu$$

remember Z complex-valued

Bivariate p.p. process {M,N}

Coherency

$$R_{MN}(\lambda) = f_{MN} / \sqrt{\{f_{MM} f_{NN}\}} \quad \text{cp. r}$$

Coherence

$$|R_{MN}(\lambda)|^2 \quad \text{cp. r}^2$$

The Empirical FT.

Data $\{0 \leq \tau_1 < \dots < \tau_N < T\}$

$$EFT : d_N^T(\lambda) = \sum_1^N \exp\{-i\lambda \tau_j\} = \int_0^T \exp\{-i\lambda t\} dN(t), \quad \lambda \text{ real}$$

Note $d_N^T(0) = N(T)$

What is the large sample distribution of the EFT?

The complex normal.

The complex normal, $N^c(\mu, \sigma^2)$, is a variate of the form

$$Y = U + iV$$

where U and V are independent $N(\operatorname{Re} \mu, \sigma^2 / 2)$, $N(\operatorname{Im} \mu, \sigma^2 / 2)$

Notes :

$$EY = \mu$$

$$\operatorname{var} Y = E |Y - \mu|^2 = \sigma^2$$

$$N^c(0,1) = IN(0,1/2) = (Z_1 + iZ_2) / \sqrt{2}$$

$$|N^c(0,1)|^2 = (Z_1^2 + Z_2^2) / 2 = \chi_2^2 / 2 = \text{exponential}$$

$$\chi_\nu^2 = Z_1^2 + \dots + Z_\nu^2 \quad Z_j \sim IN(0,1)$$

$$E\chi_\nu^2 = \nu \quad \operatorname{var} \chi_\nu^2 = 2\nu$$

Theorem. Suppose p.p. N is stationary mixing, then

i). $d_N^T(\lambda)$ is asymptotically

$$N(Tp_N, 2\pi Tf_{NN}(0)), \quad \lambda = 0$$

$$N^C(0, 2\pi Tf_{NN}(\lambda)), \quad \lambda \neq 0$$

ii). $d_N^T(\lambda_1), \dots, d_N^T(\lambda_L), \lambda_1, \dots, \lambda_L$ distinct and $\neq 0$ are asymptotically

$$IN^C(0, 2\pi Tf_{NN}(\lambda_l))$$

iii). $d^T\left(\frac{2\pi r_1}{T}\right), \dots, d^T\left(\frac{2\pi r_L}{T}\right), r_1, \dots, r_L$ distinct integers $\neq 0$ with $2\pi r_l/T \sim \lambda$

are asymptotically $IN^C(0, 2\pi Tf_{NN}(\lambda))$

Proof. Write

$$dN(t) = \int \exp\{i\lambda t\} dZ_N(\lambda) dt \quad \text{Kolmogorov}$$

then

$$d_N^T(\lambda) = \int \delta^T(\lambda - \alpha) dZ_N(\alpha)$$

with

$$\delta^T(\lambda) = \int_0^T \exp\{-i\lambda t\} dt$$

Evaluate first and second-order cumulants

Bound higher cumulants

Normal is determined by its moments

Consider

$$\begin{aligned}\text{cov}\{d_N^T(\lambda), d_N^T(\mu)\} &= \iint \delta^T(\lambda - \alpha) \delta^T(-\mu + \beta) f_{NN}(\alpha) \delta(\lambda - \alpha) d\alpha d\beta \\ &= \int \delta^T(\lambda - \alpha) \delta^T(-\mu + \alpha) f_{NN}(\alpha) d\alpha \\ &\sim 2\pi \delta^T(\lambda - \mu) f_{NN}(\lambda)\end{aligned}$$

We saw

$$\int \delta^T(\lambda - \alpha) \overline{\delta^T(\mu - \alpha)} d\alpha = 2\pi \delta^T(\lambda - \mu)$$

Comments.

Already used to study rate estimate

Tapering makes

$$\text{var } d_N^T(\lambda) \sim \int |H^T(\lambda - \alpha)| f_{NN}(\alpha) d\alpha$$

Get asymptotic independence for different frequencies

The frequencies $2\pi r/T$ are special, e.g. $\delta^T(2\pi r/T) = 0$, $r \neq 0$

Also get asymptotic independence if consider separate stretches

p-vector version involves p by p spectral density matrix $f_{NN}(\lambda)$

Estimation of the (power) spectrum.

For $\lambda \neq 0$, consider the periodogram,

$$\begin{aligned} I_{NN}^T(\lambda) &= \frac{1}{2\pi T} |d_N^T(\lambda)|^2 \\ &\sim \frac{1}{2\pi T} |N^C(0, 2\pi T f_{NN}(\lambda))|^2 \\ &\sim f_{NN}(\lambda) \chi_2^2 / 2, \quad \text{exponential} \end{aligned}$$

Estimate appears inconsistent unless $f_{NN}(\lambda) = 0$

$$\text{but note } E\{f_{NN}(\lambda) \chi_2^2 / 2\} = f_{NN}(\lambda)$$

$$\text{and } \text{var}\{f_{NN}(\lambda) \chi_2^2 / 2\} = f_{NN}(\lambda)^2$$

An estimate whose limit is a random variable

Some moments.

Complex r.v. ζ

$$E|\zeta|^2 = \text{var} \zeta + |E\zeta|^2$$

$$Ed_N^T(\lambda) = \int_0^T \exp\{-i\lambda t\} p_N dt = p_N \delta^T(\lambda)$$

so

$$E|d_N^T(\lambda)|^2 = \int |\delta^T(\lambda - \alpha)|^2 f_{NN}(\alpha) d\alpha + p_N^2 |\delta^T(\lambda)|^2$$

The estimate is asymptotically unbiased

Final term drops out if $\lambda = 2\pi r/T \neq 0$

Best to correct for mean, work with

$$d_N^T(\lambda) - p_N^T \delta^T(\lambda)$$

Periodogram values are asymptotically independent since d^T values are -

independent exponentials

Use to form estimates

Smoothed periodogram. Consider r_1, \dots, r_L distinct integers $\neq 0$
 $2\pi r_l / T$ near λ

Estimate

$$f_{NN}^T(\lambda) = \sum_l I^T(2\pi r_l / T) / L$$

CLT gives

$$f_{NN}^T(\lambda) \rightarrow f_{NN}(\lambda) \chi_{2L}^2 / 2L \text{ in distribution}$$

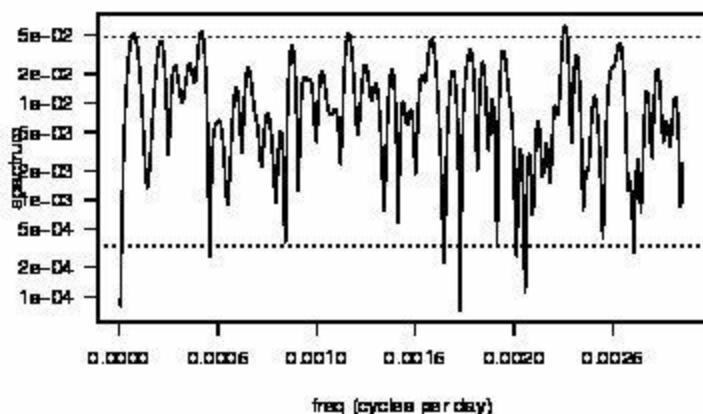

Now

$$E\{f_{NN}(\lambda) \chi_{2L}^2 / 2L\} = f_{NN}(\lambda) \quad \text{var}\{f_{NN}(\lambda) \chi_{2L}^2 / 2L\} = f_{NN}(\lambda)^2 / L$$

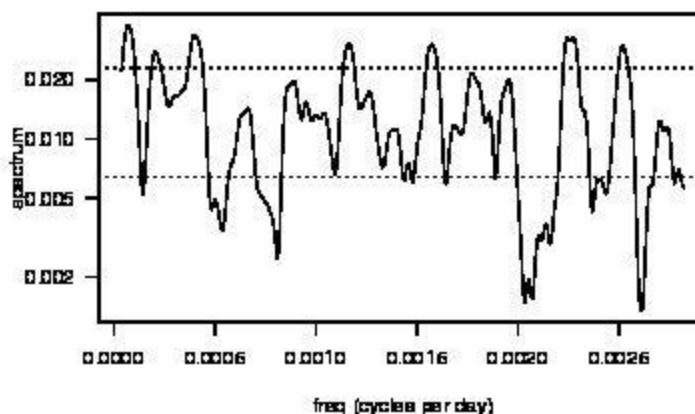

Can control variance. Try several L's

California earthquakes 1932–1992

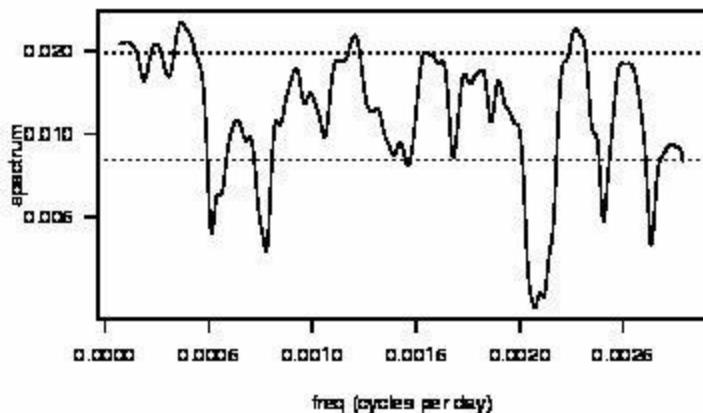

L = 1

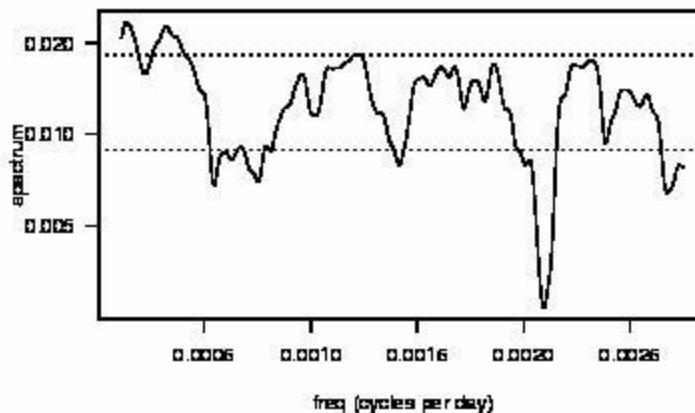

L = 10

L = 20

L = 30

Approximate marginal confidence intervals

$$\Pr\{\log f^T(\lambda) + \log v / \chi_v^2(1 - \alpha/2) < \log f(\lambda) < \log f^T(\lambda) + \log v / \chi_v^2(\alpha/2)\}$$

Notes.

variance stabilized by log

set CI about mean level

simultaneous band via extreme value distribution

might take $L \rightarrow \infty$ for consistent estimate

might take weighted mean, or tapered FT

might split data, $T = LV$

More on choice of L

Consider

$$E\{f^T(\lambda)\} = E\{\sum_l I^T(\lambda_l)/L\}, \quad \lambda_l = 2\pi r_l/T \approx \lambda = 2\pi r/T$$

$$\begin{aligned} &= \int \frac{1}{L} \sum_l \frac{1}{2\pi T} \left[\sin T(\lambda_l - \alpha)/2) / ((\lambda_l - \alpha)/2) \right]^2 f(\alpha) d\alpha \\ &= \int W^T(\lambda - \alpha) f(\alpha) d\alpha \end{aligned}$$

Choice of L affects width of $W^T(\cdot)$

$L 2\pi/T$ radians

If f is not constant, f^T biased

Approximation to bias

Suppose $W^T(\boldsymbol{\alpha}) = B_T^{-1}W(B_T^{-1}\boldsymbol{\alpha})$

$$\begin{aligned}& \int W^T(\boldsymbol{\alpha}) f(\lambda - \boldsymbol{\alpha}) d\boldsymbol{\alpha} \\&= \int W(\boldsymbol{\beta}) f(\lambda - B_T \boldsymbol{\beta}) d\boldsymbol{\beta} \\&= \int W(\boldsymbol{\beta}) [f(\lambda) - B_T \boldsymbol{\beta} f'(\lambda) + B_T^2 \boldsymbol{\beta}^2 f''(\lambda)/2 + \dots] d\boldsymbol{\beta} \\&= f(\lambda) \int W(\boldsymbol{\beta}) d\boldsymbol{\beta} - B_T f'(\lambda) \int \boldsymbol{\beta} W(\boldsymbol{\beta}) d\boldsymbol{\beta} + B_T^2 f''(\lambda) \int \boldsymbol{\beta}^2 W(\boldsymbol{\beta}) d\boldsymbol{\beta} / 2 + \dots\end{aligned}$$

For W symmetric $\int \boldsymbol{\beta} W(\boldsymbol{\beta}) d\boldsymbol{\beta} = 0$

Indirect estimate

$$\frac{p_N^T}{2\pi} + \frac{1}{2\pi} \int \exp\{-i\lambda u\} w^T(u) q_{NN}^T(u) du$$

Could approximate p.p. by 0-1 time series and use t.s.

Point process system.

An operation carrying a point process, M , into another, N

$$N = S[M]$$

$S = \{\text{input, mapping, output}\}$

$$\Pr\{dN(t)=1|M\} = \{\mu + \int a(t-u)dM(u)\}dt$$

System identification: determining the characteristics of a system from inputs and corresponding outputs

$$\{M(t), N(t); 0 \leq t < T\}$$

Like regression vs. bivariate

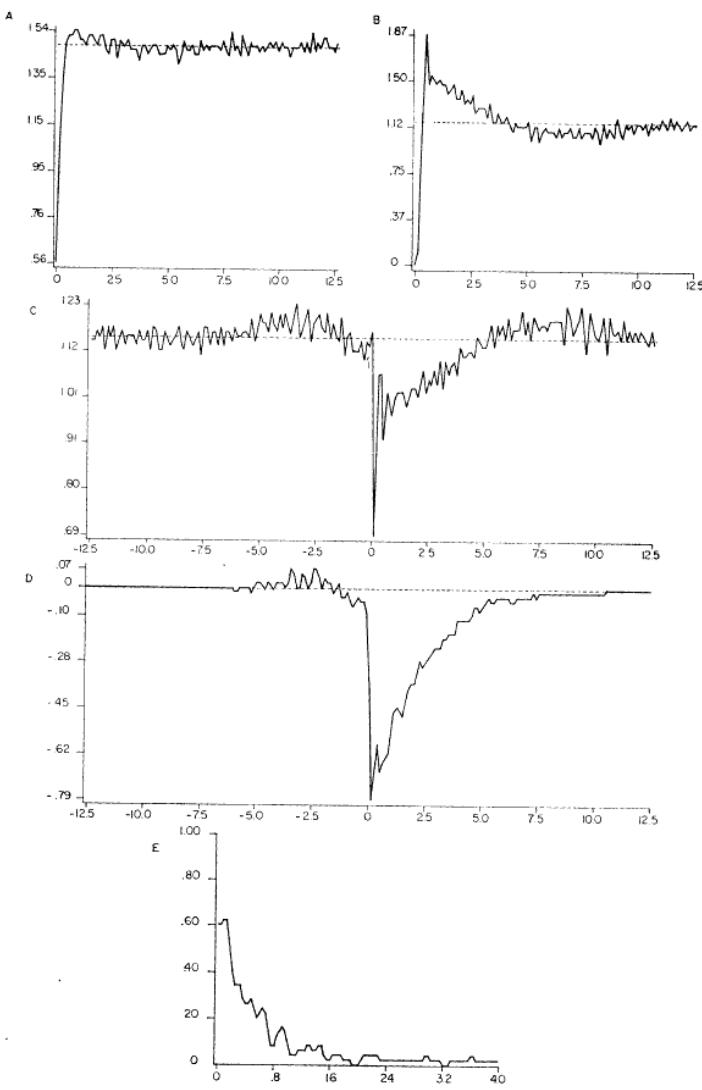

FIG. 2.

Realizable case.

$$a(u) = 0 \text{ } u < 0$$

$A(\lambda)$ is of special form

e.g. $N(t) = M(t-\tau)$

$$\arg A(\lambda) = -\lambda\tau$$

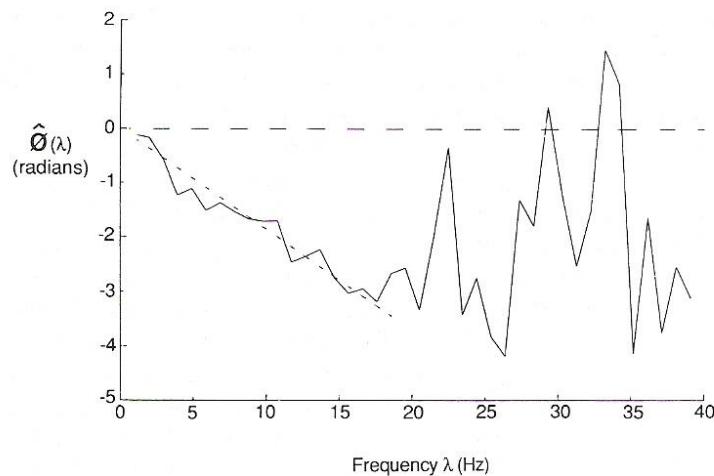

FIG. 4. Estimated phase, $\hat{\Phi}(\lambda)$, for the response of a muscle spindle II ending to stimulation of a static fusimotor axon. The coherence for the same relation is illustrated in Fig. 3d. The dashed line represents the linear regression line fitted to the phase curve over the range of frequencies where the coherence shown in Fig. 3d is significant. The slope of the linear phase curve gives an estimated delay of 29.9 msec with 95% confidence limits of 29.9 ± 2.18 msec.

Advantages of frequency domain approach.
