

Testing with one real parameter

10/12/2023

Outline

- 1) Uniformly most powerful test
- 2) Two-tailed tests

Uniformly most powerful tests

General setup: $\mathcal{P}, \Theta_0, \Theta_1$

Def If $\phi^*(x)$ has sig. level α , and for any other level- α test ϕ we have

$$\mathbb{E}_{\theta} \phi^* \geq \mathbb{E}_{\theta} \phi \quad \forall \theta \in \Theta_1,$$

then ϕ^* is uniformly most powerful (UMP)

Typically only exist for 1-sided testing in certain 1-parameter families.

Def A model \mathcal{P} is identifiable if

$$\theta_1 \neq \theta_2 \Rightarrow P_{\theta_1} \neq P_{\theta_2} \quad (\exists A : P_{\theta_1}(A) \neq P_{\theta_2}(A))$$

Def Assume $\mathcal{P} = \{P_{\theta} : \theta \in \Theta \subseteq \mathbb{R}\}$ has densities p_{θ} , and is identifiable. We say \mathcal{P} has

monotone likelihood ratios (MLR) if

there is some statistic $T(X)$ s.t.

$$\frac{p_{\theta_2}}{p_{\theta_1}}(x) \text{ is a nondecreasing function of } T(x),$$

for any $\theta_1 < \theta_2$ [same $T(x)$ for all θ 's]

$$\left(\frac{c}{0} = \infty \text{ if } c > 0, \quad \frac{0}{0} \text{ undef.} \right)$$

Ex. Exp. fam: $e^{(\eta_1 - \eta_0) \sum T(x_i) - n(A(\eta_1) - A(\eta_0))}$ \nearrow in $\sum T(x_i)$

Theorem Assume \mathcal{P} has MLR, test $H_0: \theta \leq \theta_0$

vs $H_1: \theta > \theta_0$ at level $\alpha \in (0, 1)$

$$\text{Let } \phi^*(x) = \begin{cases} 0 & T(x) < c \\ \gamma & T(x) = c \\ 1 & T(x) > c \end{cases},$$

with c, γ chosen so $\mathbb{E}_{\theta_0} \phi^*(x) = \alpha \in (0, 1)$

a) ϕ^* is a UMP level- α test

b) If $\theta_1 < \theta_0$ then ϕ^* minimizes $\mathbb{E}_{\theta_1} \phi(x)$

among all tests with $\mathbb{E}_{\theta_0} \phi(x) = \alpha$

Proof

a) Suppose $\theta_1 > \theta_0$ and $\tilde{\phi}$ has level $\leq \alpha$

$$\Rightarrow \mathbb{E}_{\theta_1} \phi^*(x) \geq \mathbb{E}_{\theta_1} \tilde{\phi}(x) \text{ since } \phi^* \text{ is}$$

a LRT for $H_0: \theta = \theta_0$ vs. $H_1: \theta = \theta_1$

c) $\theta_1 < \theta_0$, assume $\mathbb{E}_{\theta_0} \tilde{\phi}(x) = \mathbb{E}_{\theta_0} \phi^*(x) = \alpha$

Both $1 - \phi^*$, $1 - \tilde{\phi}$ are tests of $H_0: \theta = \theta_0$ vs $H_1: \theta = \theta_1$

both have sig. level $1 - \alpha$

$1 - \phi^*$ is a LRT since $\frac{f_1}{f_0}(x)$ is non-incr. in $T(x)$

$$\Rightarrow \mathbb{E}_{\theta_1} (1 - \tilde{\phi}) \leq \mathbb{E}_{\theta_1} (1 - \phi^*) = 1 - \alpha \quad \square$$

Intuition ϕ^* is a LRT for $H_0: \theta = \theta_0$ vs $H_1: \theta = \theta_1$
for any pair $\theta_0 < \theta_1$ (sig. level depends on θ_0)

UMP test: Picture

One-sided tests in general

$$\mathcal{P} = \{P_\theta : \theta \in \Theta \subseteq \mathbb{R}\}, \quad \theta_0 \in \Theta$$

$H_0: \theta \overset{\geq}{\leq} \theta_0$ vs $H_1: \theta \overset{<}{>} \theta_0$ called one-sided hypothesis

Often, no UMP test exists

Ex. Laplace: $X_1, \dots, X_n \stackrel{iid}{\sim} \frac{1}{2} e^{-|x-\theta|}$

LRT for $H_0: \theta = \theta_0$ vs $H_1: \theta = \theta_1 (> \theta_0)$

$$\begin{aligned} \log\left(\frac{P_1(x)}{P_0(x)}\right) &= \sum_{i=1}^n |x_i - \theta_0| - |x_i - \theta_1| \\ &= \sum T(x_i) \end{aligned}$$

$$T(x) = \begin{cases} \theta_0 - \theta_1 & x \leq \theta_0 \\ 2x - \theta_0 - \theta_1 & \theta_0 \leq x \leq \theta_1 \\ \theta_1 - \theta_0 & x \geq \theta_1 \end{cases}$$

Very dependent on specific values of θ_0 and θ_1

Test $H_0: \theta \leq 0$ vs $H_1: \theta > 0$: No UMP test

Test $H_0: \theta = 0$ vs $H_1: \theta = \varepsilon, \varepsilon \downarrow 0$:

$$\sum T(x_i) = -\varepsilon \#\{x_i \leq 0\} + \varepsilon \#\{x_i \geq \varepsilon\} + \sum_{x_i \in [0, \varepsilon]} 2x_i - \varepsilon$$

$$\frac{1}{\varepsilon} \sum T(x_i) \xrightarrow{\varepsilon \rightarrow 0} \#\{x_i > 0\} - \#\{x_i \leq 0\} = 2\#\{x_i > 0\} - n$$

$$n + \frac{1}{2\varepsilon} \sum T(x_i) \xrightarrow{\varepsilon \rightarrow 0} \#\{x_i > 0\} \stackrel{\theta=0}{\sim} \text{Binom}(n, \frac{1}{2}) \quad \underline{\text{Sign test}}$$

Stochastically incr.

Def A real-valued statistic $T(X)$ is stochastically increasing in Θ if

$\mathbb{P}_\Theta(T(X) \leq t)$ is non-incr. in Θ , $\forall t$

If $\phi(x)$ is right-tailed test based on $T(X)$:

$$\phi(x) = \mathbb{1}\{T(X) > c\} + \gamma \mathbb{1}\{T(X) = c\}$$

and $T(X)$ is stochastically increasing in Θ ,

$$\mathbb{E}_\Theta \phi(X) = (1-\gamma) \mathbb{P}_\Theta(T > c) + \gamma \mathbb{P}_\Theta(T \geq c) \nearrow_{\text{in } \Theta}$$

\mathbb{E}_X $X_i \stackrel{\text{iid}}{\sim} \rho(x-\theta)$ (location family)
 $T(X) =$ sample mean, median, sign statistic

\mathbb{E}_X $X_i \stackrel{\text{iid}}{\sim} \frac{1}{\theta} \rho(x/\theta)$ (scale family)
 $T(X) = \sum X_i^2$ or median($|X_1|, \dots, |X_n|$)

Two-sided Alternatives

Setup: $\mathcal{P} = \{P_\theta : \theta \in \Theta \subseteq \mathbb{R}\}$, $\theta_0 \in \Theta^0$

Test $H_0: \theta = \theta_0$ vs. $H_1: \theta \neq \theta_0$

(Can be generalized naturally to $H_0: \theta \in [\theta_1, \theta_2]$)

Two-tailed test rejects when $T(X)$ is "extreme"

$$\phi(x) = \begin{cases} 1 & T(x) > c_2 \text{ or } T(x) < c_1 \\ 0 & T(x) \in (c_1, c_2) \\ \gamma_i & T(x) = c_i \end{cases}$$

Two ways to reject. How to balance?

For symmetric distributions like $N(\theta, 1)$, natural choice is to equalize "lobes" of rej. region

$$\phi_2(x) = \mathbb{1}\{|x - \theta_0| > z_{\alpha/2}\} \text{ for } H_0: \theta = \theta_0$$

For asymmetric dists, or interval null $H_0: \theta \in [\theta_1, \theta_2]$, more complicated

Equal-tailed & unbiased tests

Point null ($H_0: \theta = \theta_0$)

$$\text{Let } \alpha_1 = P_{\theta_0}(T < c_1) + \gamma_1 P_{\theta_0}(T = c_1)$$

$$\alpha_2 = P_{\theta_0}(T > c_2) + \gamma_2 P_{\theta_0}(T = c_2)$$

Valid if $\alpha_1 + \alpha_2 = \alpha$ (α_1 is "free parameter")

Idea 1: Equal-tailed test : $\alpha_1 = \alpha_2 = \frac{\alpha}{2}$

Ex $X \sim \text{Exp}(\theta)$, test $H_0: \theta = 1$

$$\text{Solve for cutoffs: } \frac{\alpha}{2} = P_1(X \leq c_1) = 1 - e^{-c_1} \Rightarrow c_1 = -\log(1 - \frac{\alpha}{2})$$

$$1 - \frac{\alpha}{2} = 1 - e^{-c_2} \Rightarrow c_2 = -\log(\frac{\alpha}{2})$$

$$\phi(x) = 1\{X < -\log(1 - \frac{\alpha}{2})\} + 1\{X > -\log(\frac{\alpha}{2})\}$$

$$\beta_\phi(\theta) = P_\theta \left\{ \frac{X}{\theta} < \frac{-\log(1 - \frac{\alpha}{2})}{\theta} \right\} + P_\theta \left\{ \frac{X}{\theta} > \frac{-\log(\frac{\alpha}{2})}{\theta} \right\}$$

$$= 1 - (1 - \frac{\alpha}{2})^{1/\theta} + (\frac{\alpha}{2})^{1/\theta} = \alpha \text{ for } \theta = 1 \text{ or } 1/2$$

Unbiased tests

Def $\phi(x)$ is unbiased if $\inf_{\theta \in \Theta} \mathbb{E}_{\theta} \phi(x) \geq \alpha$

Idea 2: Unbiased test: ensure $\min_{\theta} \beta_{\phi}(\theta) = \alpha$

Choose c_1, γ_1 and c_2, γ_2 to solve:

$$\beta_{\phi}(\theta_0) = \alpha \quad (2 \text{ equations, "2" unknowns})$$

$$\frac{d\beta_{\phi}}{d\theta}(\theta_0) = 0$$

Ex: 1-parameter exp. family, $H_0: \eta = \eta_0$ vs $H_1: \eta \neq \eta_0$

$$X \sim e^{\eta T(x) - A(\eta)} h(x) \quad (\text{MLR in } T(x))$$

Assume $T(x)$ continuous, solve

$$\alpha = \beta_{\phi}(\eta_0) = \mathbb{P}_{\eta_0}(T < c_1) + \mathbb{P}_{\eta_0}(T > c_2)$$

$$0 = \frac{d\beta_{\phi}}{d\eta}(\eta_0) = \text{Cov}_{\eta_0}(\phi(T), T)$$

$$= \mathbb{E}_{\eta_0}[(\phi(T) - \alpha) T(x)]$$

Theorem Assume $X_i \stackrel{iid}{\sim} e^{\theta T(x) - A(\theta)} h(x)$

$H_0: \theta \in [\theta_1, \theta_2]$ vs $H_1: \theta < \theta_1$ or $\theta > \theta_2$
(possibly $\theta_1 = \theta_2$)

Then

a) The unbiased test based on $\sum T(x_i)$ with sig. level $= \alpha$ is UMP among all unbiased tests (UMPU) (rejecting for extreme values of)

b) If $\theta_1 < \theta_2$ the UMPU test can be found by solving for c_i, γ_i s.t. $\mathbb{E}_{\theta_1} \phi = \mathbb{E}_{\theta_2} \phi = \alpha$

c) If $\theta_1 = \theta_2 = \theta_0$ the UMPU test can be found by solving for c_i, γ_i s.t. $\mathbb{E}_{\theta_0} \phi(x) = \alpha$ and

$$\frac{d\beta_\phi}{d\theta}(\theta_0) = \mathbb{E}_{\theta_0} [\sum T(x_i) (\phi(x) - \alpha)] = 0$$

(Proof in Keener)
