
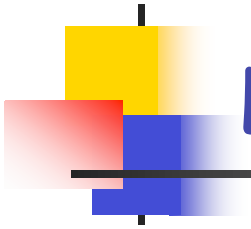
Community Structure in Large Social and Information Networks

Michael W. Mahoney

Stanford University

(Joint work with Kevin Lang and Anirban Dasgupta of Yahoo, and also Jure Leskovec of CMU.)

(For more info, see: http://cs.stanford.edu/people/mmahoney)



Lots and lots of large data!

- DNA micro-array data and DNA SNP data
- High energy physics experimental data
- Hyper-spectral medical and astronomical image data
- Term-document data
- Medical literature analysis data
- Collaboration and citation networks
- Internet networks and web graph data
- Advertiser-bidded phrase data
- Static and dynamic social network data

Networks and networked data

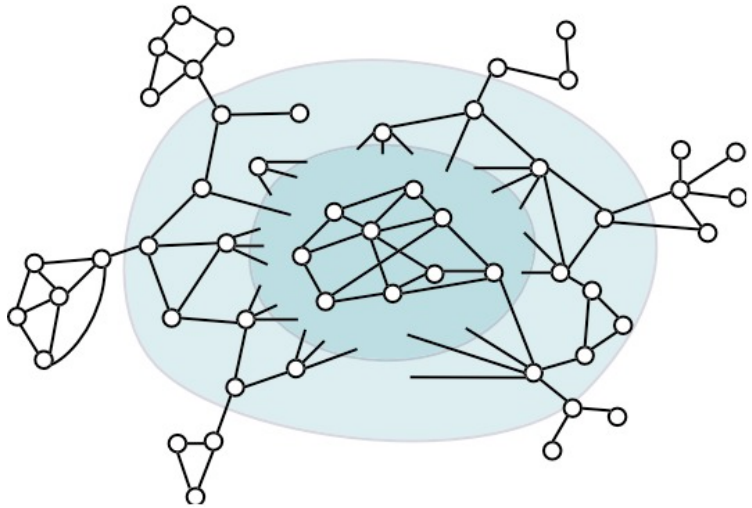
Lots of "networked" data!!

- technological networks
  - AS, power-grid, road networks
- biological networks
  - food-web, protein networks
- social networks
  - collaboration networks, friendships
- information networks
  - co-citation, blog cross-postings, advertiser-bidded phrase graphs...
- language networks
  - semantic networks...
- ...

Interaction graph model of networks:

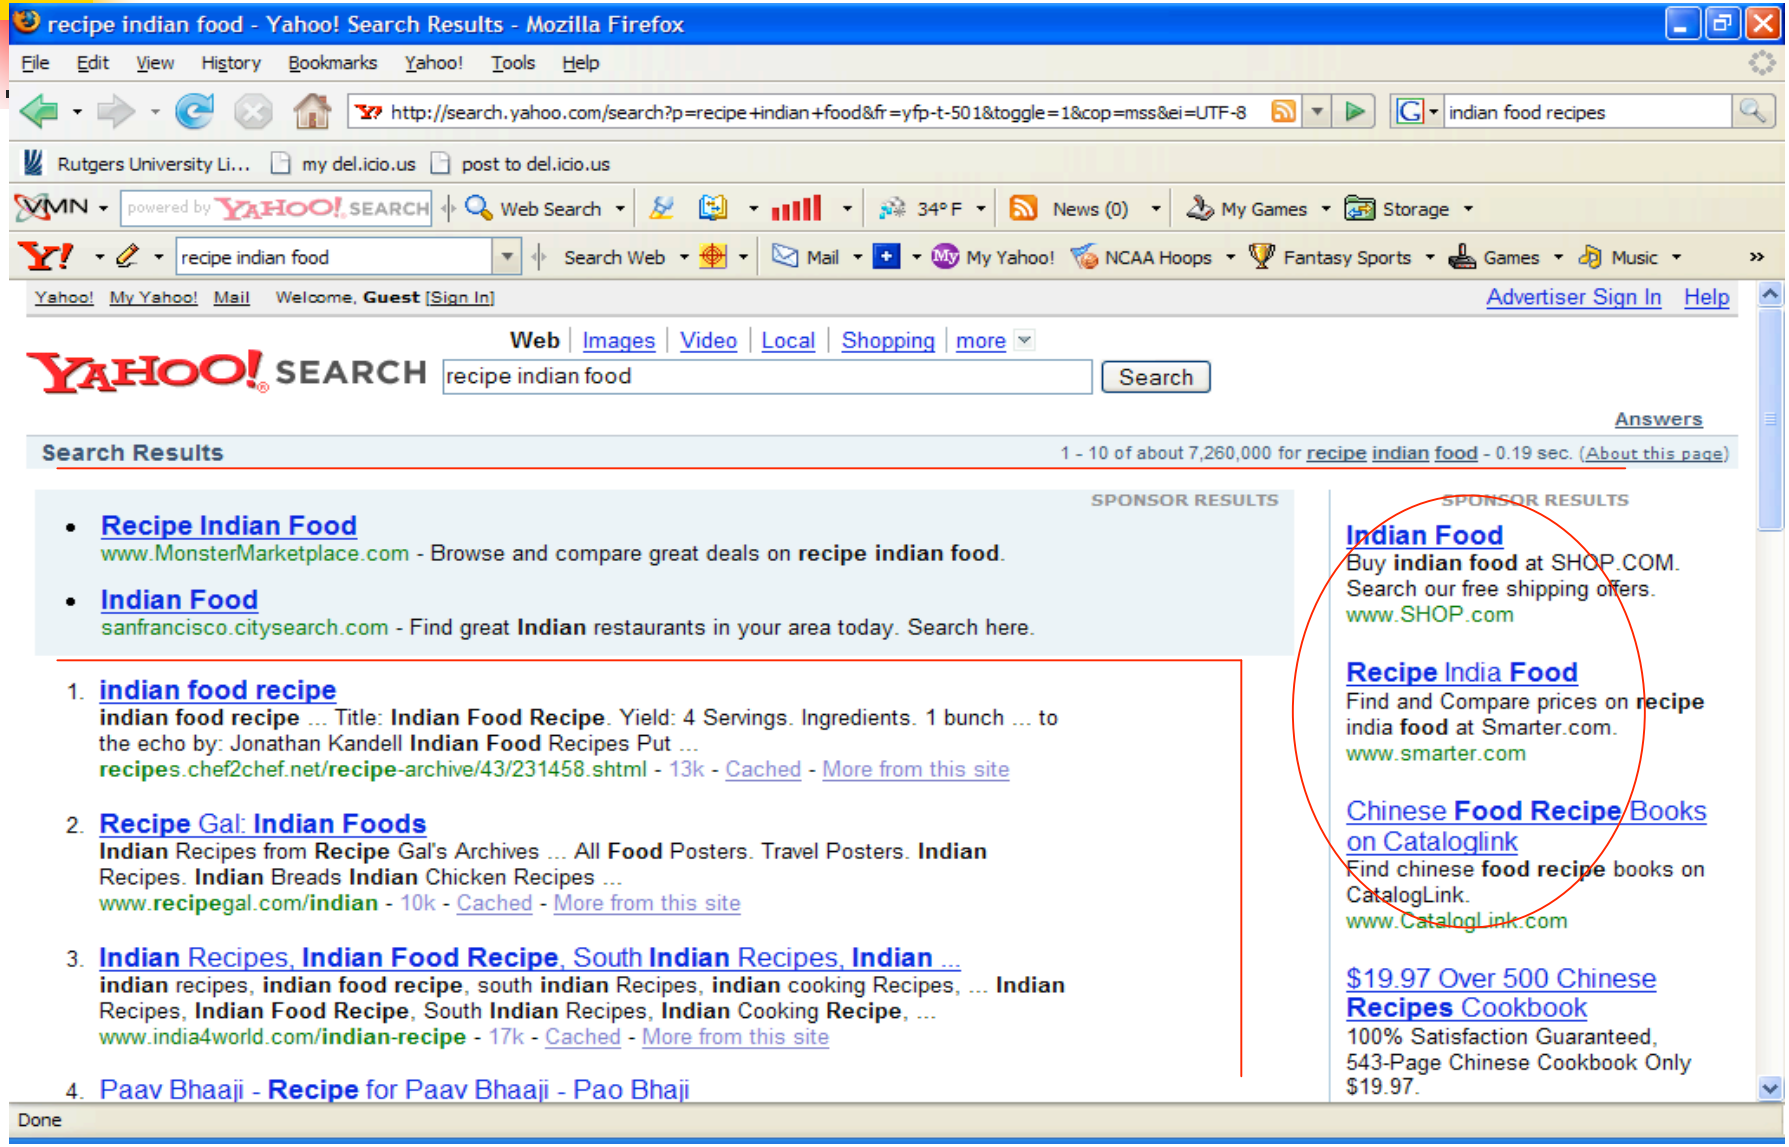
- Nodes represent "entities"
- Edges represent "interaction"

between pairs of entities

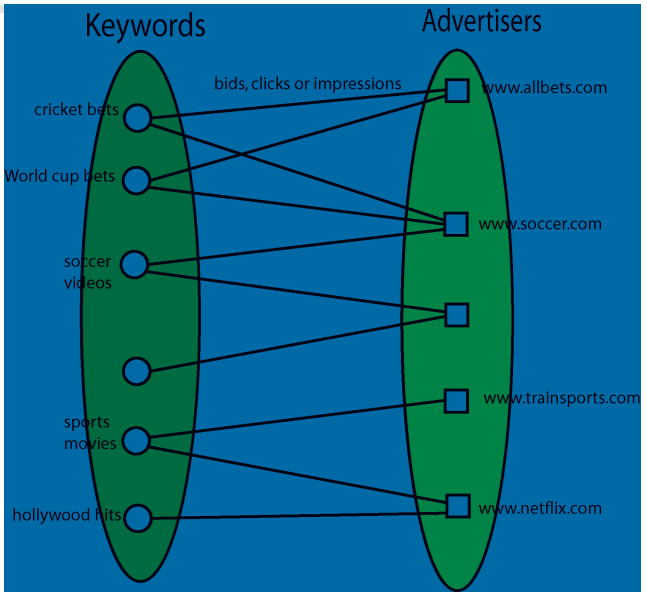


Sponsored ("paid") Search

Text-based ads driven by user query



Sponsored Search Problems



Keyword-advertiser graph:

- provide new ads
- maximize CTR, RPS, advertiser ROI

"Community-related" problems:

- Marketplace depth broadening:

  find new advertisers for a particular query/submarket

- Query recommender system:

  suggest to advertisers new queries that have high probability of clicks

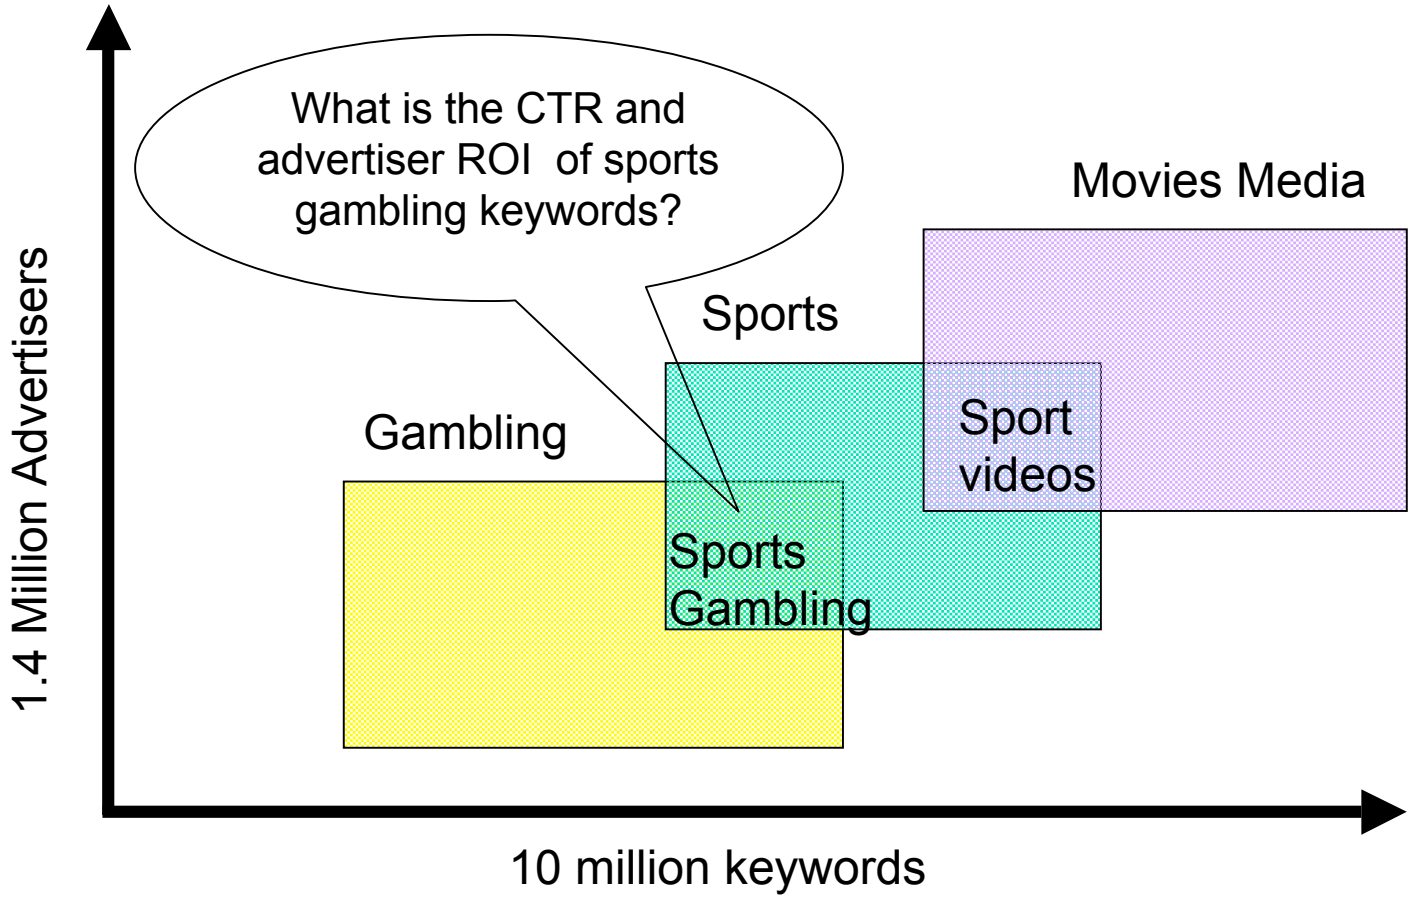
- Contextual query broadening:

  broaden the user's query using other context information

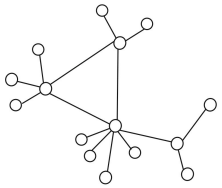
Micro-markets in sponsored search

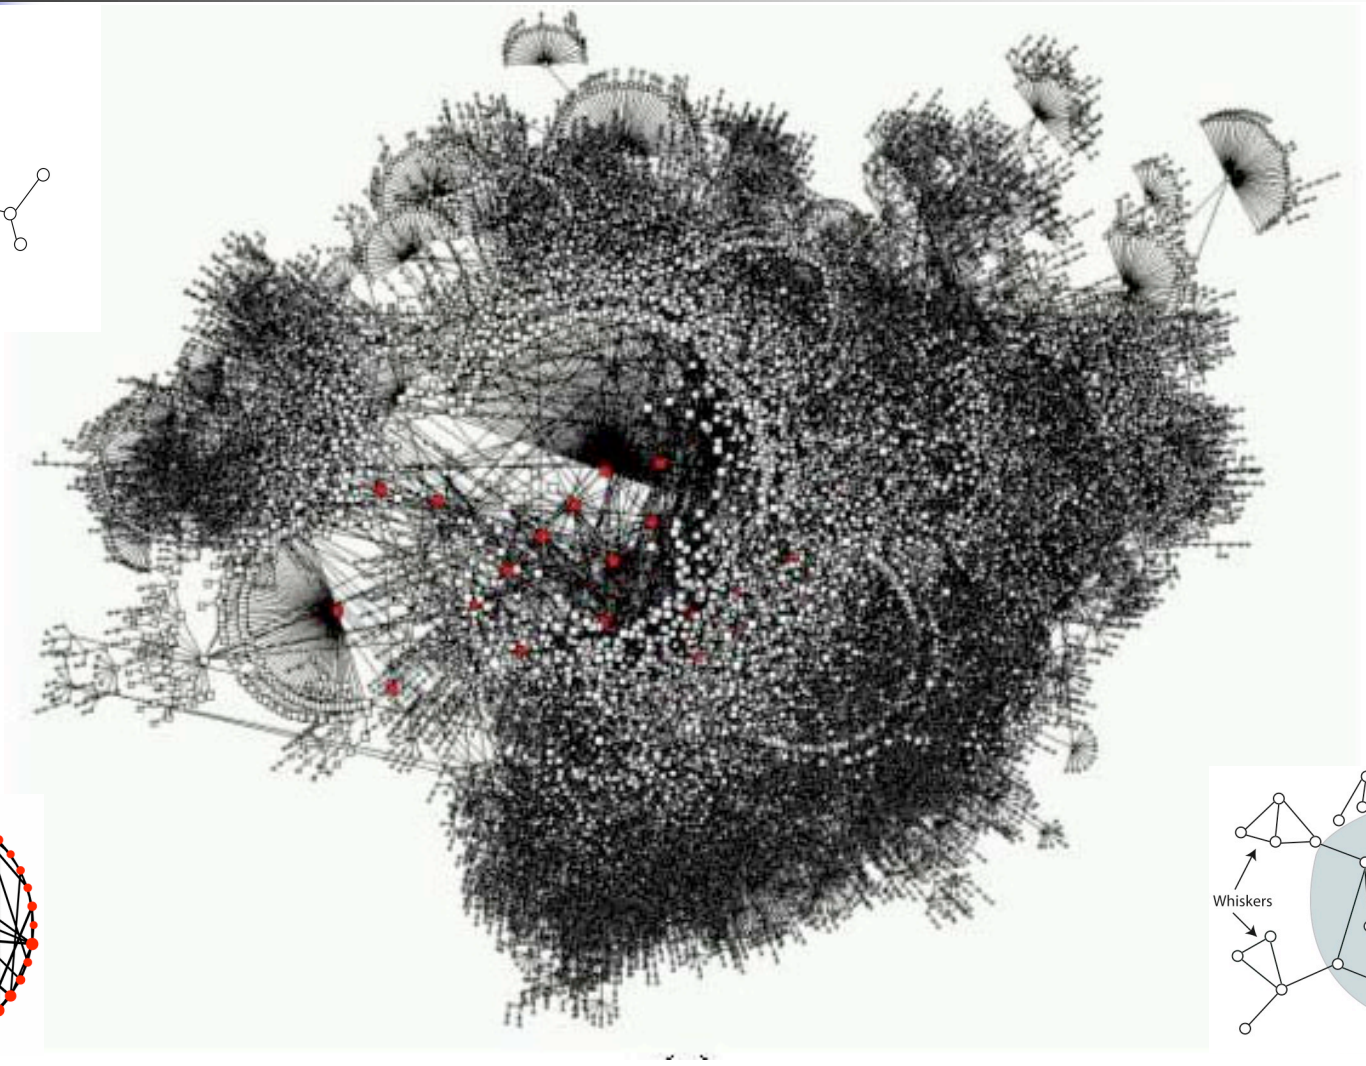
Goal: Find *isolated* markets/clusters with *sufficient money/clicks* with *sufficient coherence*.

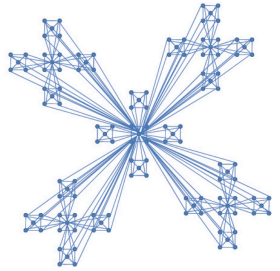
Ques: Is this even possible?

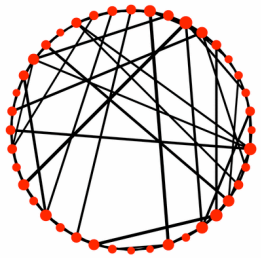


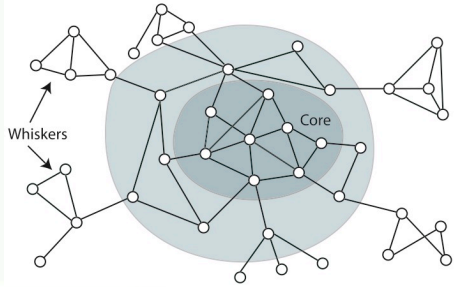
What do these networks "look" like?

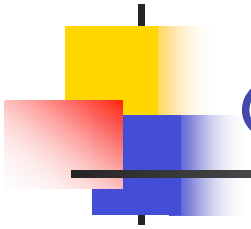












Questions of interest ...

What are degree distributions, clustering coefficients, diameters, etc.?

Heavy-tailed, small-world, expander, geometry+rewiring, local-global decompositions, ...

Are there natural clusters, communities, partitions, etc.?

Concept-based clusters, link-based clusters, density-based clusters, ...

(e.g., *isolated* micro-markets with *sufficient money/clicks* with *sufficient coherence*)

How do networks grow, evolve, respond to perturbations, etc.?

Preferential attachment, copying, HOT, shrinking diameters, ...

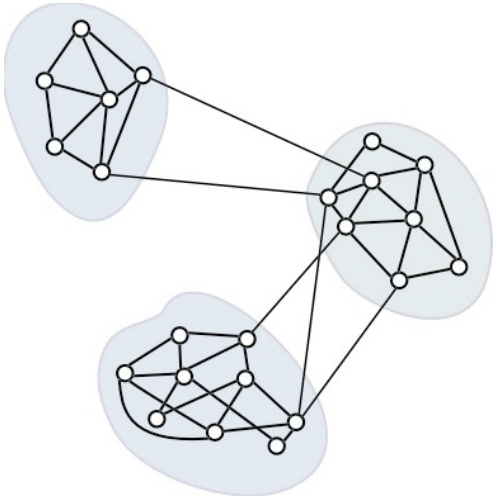
How do dynamic processes - search, diffusion, etc. - behave on networks?

Decentralized search, undirected diffusion, cascading epidemics, ...

How best to do learning, e.g., classification, regression, ranking, etc.?

Information retrieval, machine learning, ...

Clustering and Community Finding



- Linear (Low-rank) methods

  If Gaussian, then low-rank space is good.

- Kernel (non-linear) methods

  If low-dimensional manifold, then kernels are good

- Hierarchical methods

  Top-down and botton-up -- common in the social sciences

- Graph partitioning methods

  Define "edge counting" metric -- conductance, expansion, modularity, etc. -- in interaction graph, then optimize!

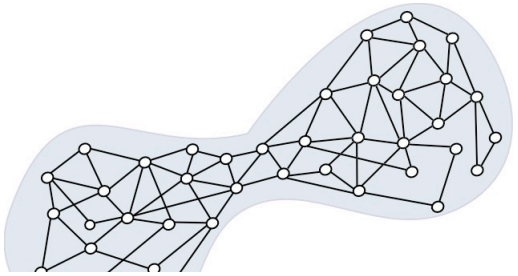
"It is a matter of common experience that communities exist in networks ... Although not precisely defined, communities are usually thought of as sets of nodes with better connections amongst its members than with the rest of the world."

Communities, Conductance, and NCPPs

Let A be the adjacency matrix of G=(V,E).

The conductance ϕ of a set S of nodes is:

$$\phi(S) = \frac{\sum_{i \in S, j \notin S} A_{ij}}{\min\{A(S), A(\overline{S})\}}$$



$$A(S) = \sum_{i \in S} \sum_{j \in V} A_{ij}$$

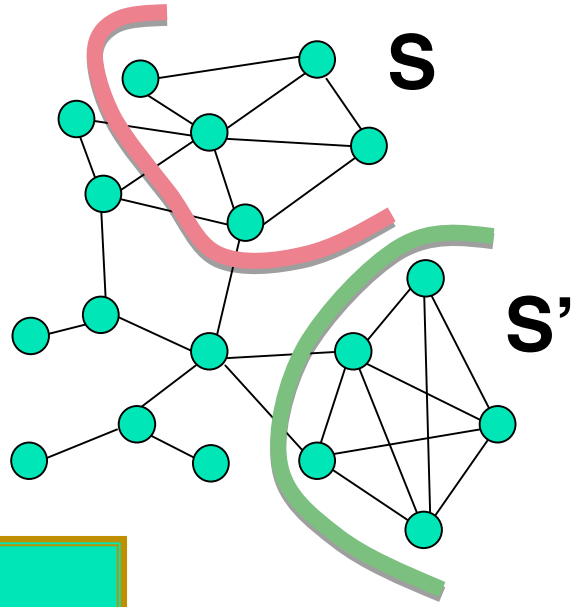
The Network Community Profile (NCP) Plot of the graph is:

$$\Phi(k) = \min_{S \subset V, |S| = k} \phi(S)$$

Just as conductance captures the "gestalt" notion of cluster/community quality, the NCP plot measures cluster/community quality as a function of size.

Community Score: Conductance

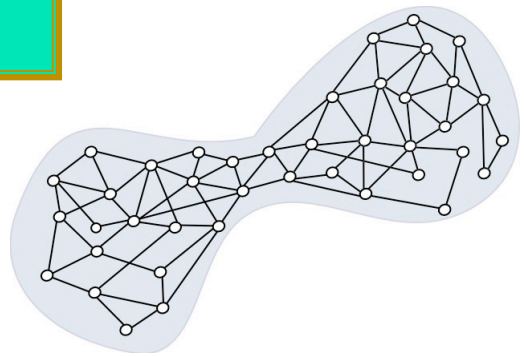
- How community like is a set of nodes?
- Need a natural intuitive measure:



- **Conductance** (normalized cut)

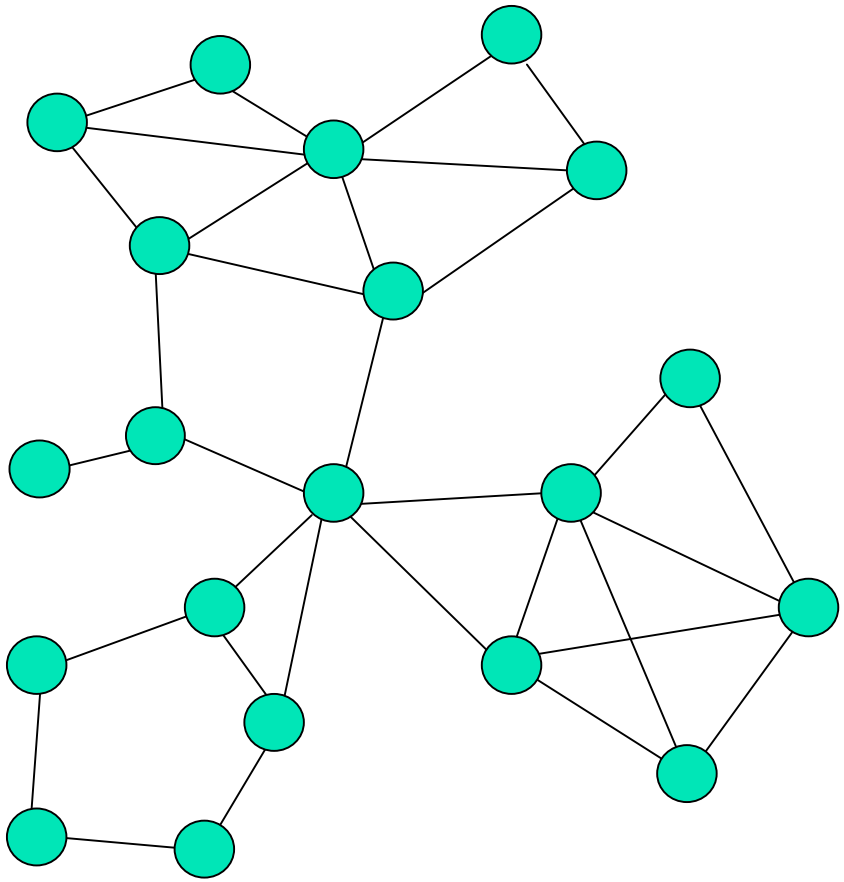
ϕ(S) = # edges cut / # edges inside

- **Small ϕ(S)** corresponds to more community-like sets of nodes



Community Score: Conductance

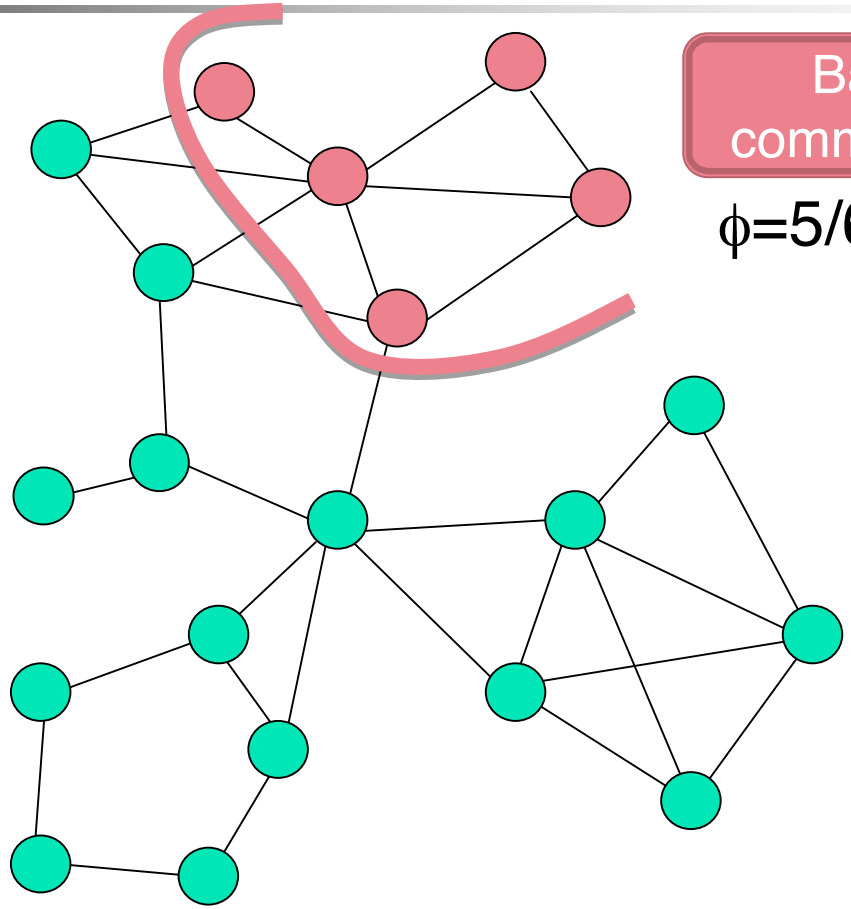
What is "best" community of 5 nodes?



Score: $\phi(S)$ = # edges cut / # edges inside

Community Score: Conductance

What is "best" community of 5 nodes?



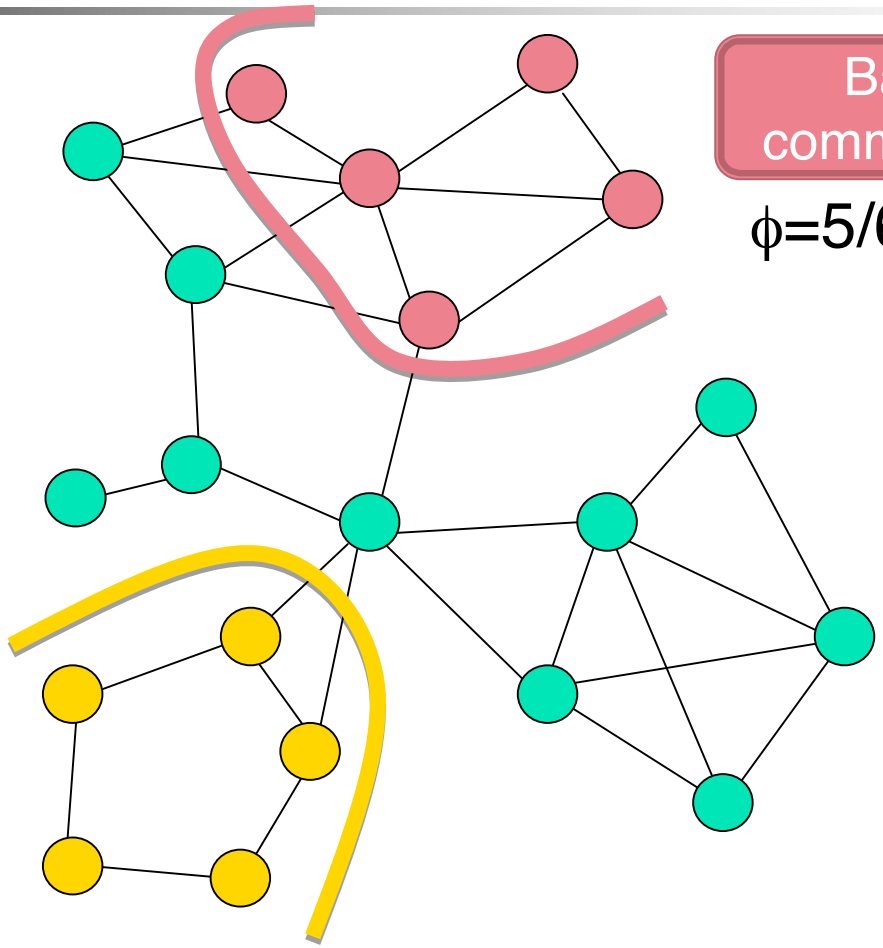
Bad community

ϕ=5/6 = 0.83

Score: ϕ(S) = # edges cut / # edges inside

Community Score: Conductance

What is "best" community of 5 nodes?



Bad community

ϕ=5/6 = 0.83

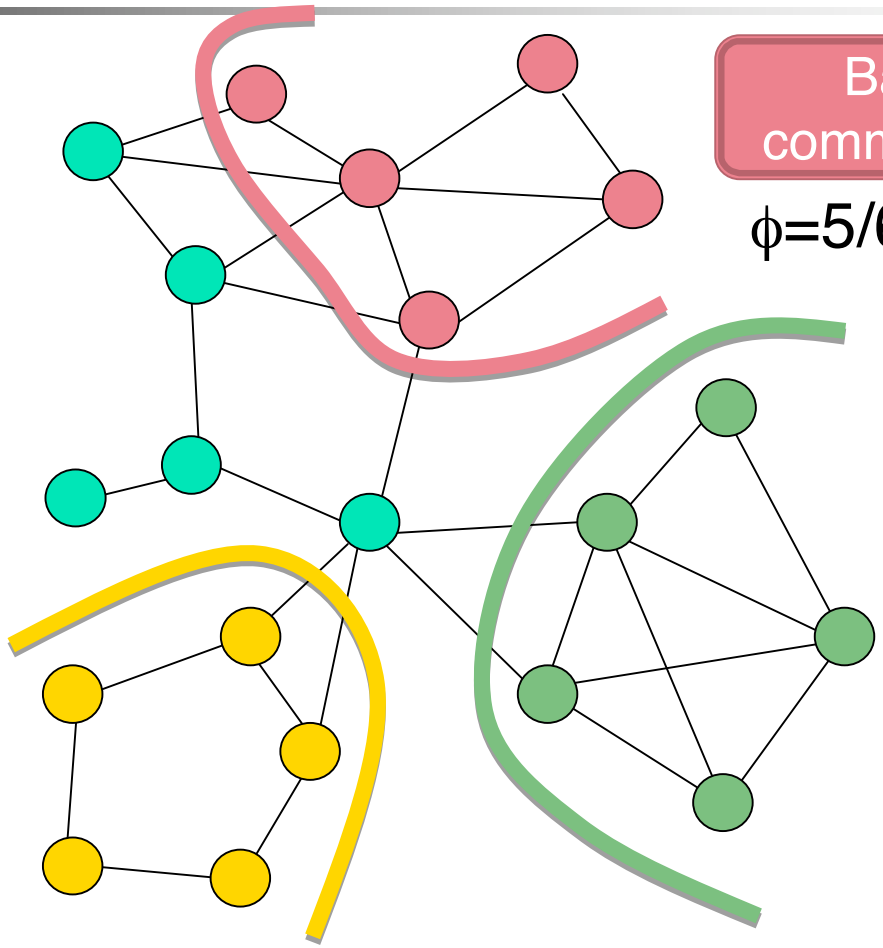
Better community

ϕ=2/5 = 0.4

Score: ϕ(S) = # edges cut / # edges inside

Community Score: Conductance

What is "best" community of 5 nodes?



Bad community

ϕ=5/6 = 0.83

Best community

ϕ=2/8 = 0.25

Better community

ϕ=2/5 = 0.4

Score: $\phi(S)$ = # edges cut / # edges inside

Network Community Profile Plot

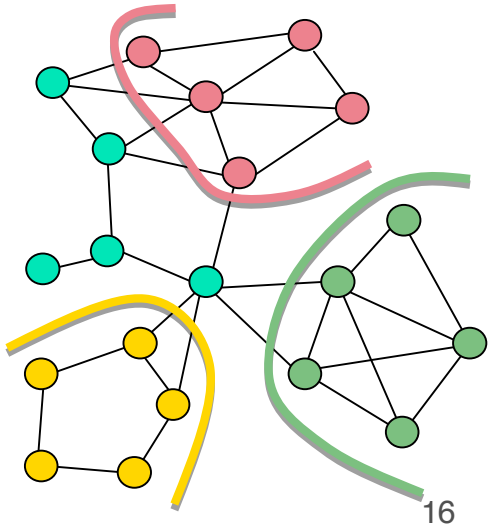
- We define:

  Network community profile (**NCP**) plot

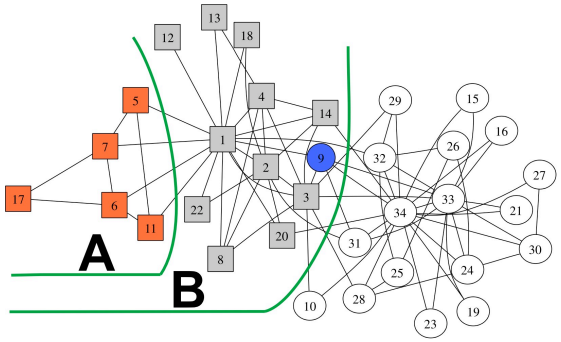
  Plot the score of best community of size k

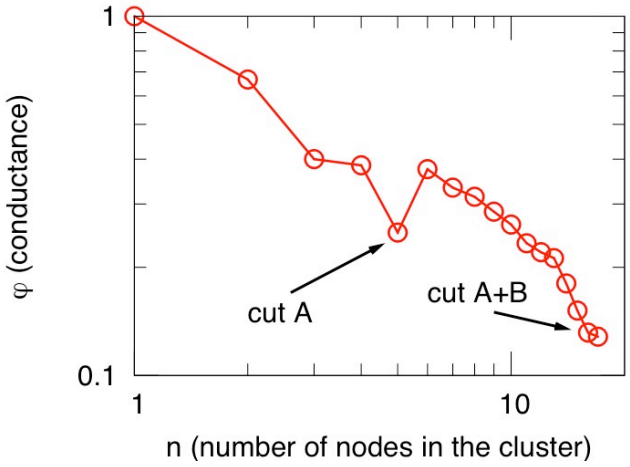
$$\Phi(k) = \min_{S \subset V, |S|=k} \phi(S)$$

- Search over all subsets of size k and find best: ϕ(k=5) = 0.25
- NCP plot is intractable to compute
- Use approximation algorithms

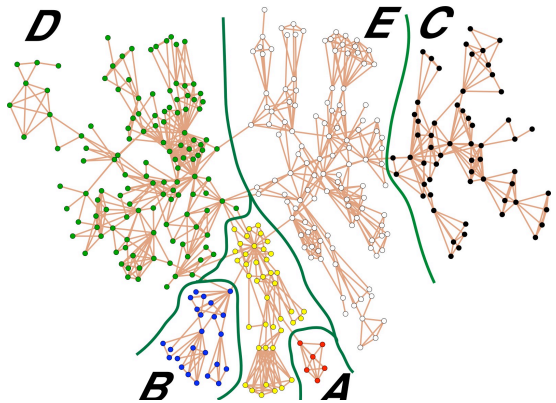


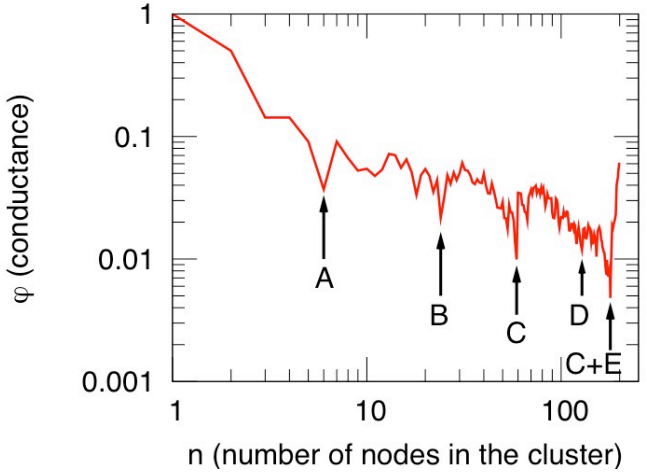
Widely-studied small social networks





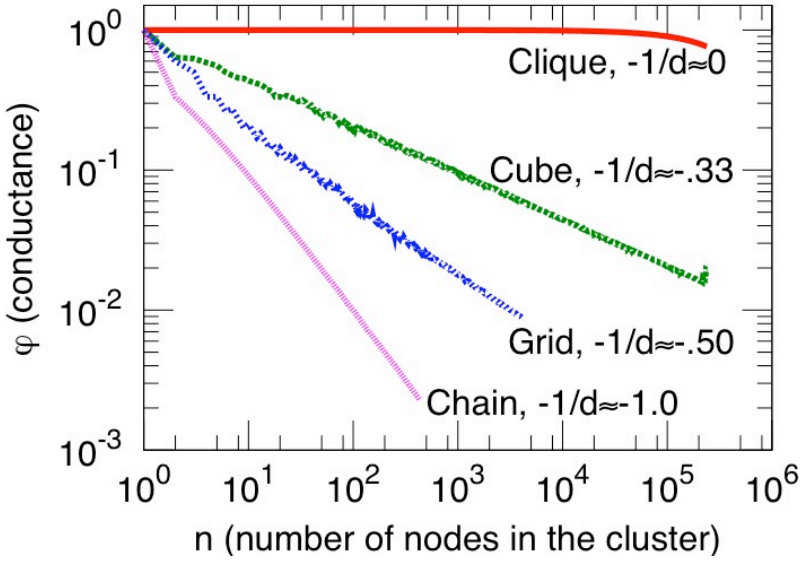
Zachary's karate club



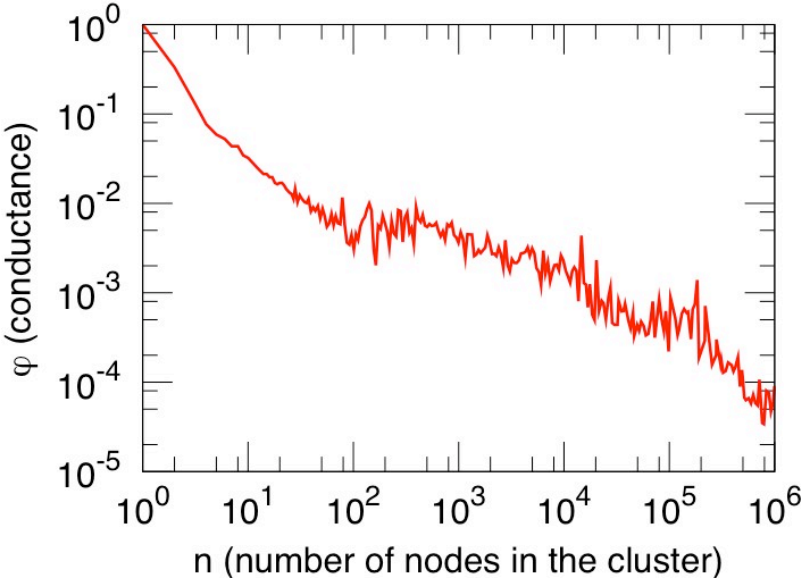


Newman's Network Science

"Low-dimensional" graphs (and expanders)

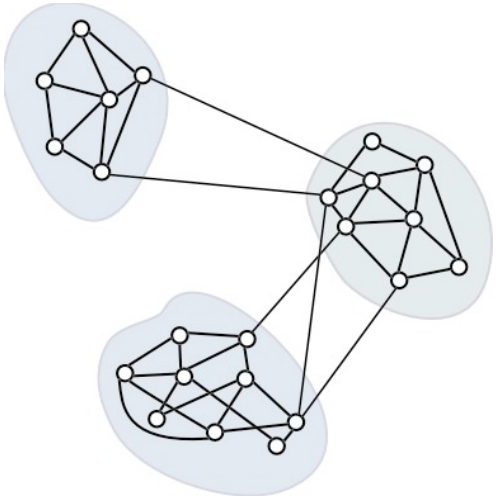


d-dimensional meshes



RoadNet-CA

What do large networks look like?



Downward sloping NCPP

small social networks (validation)

"low-dimensional" networks (intuition)

hierarchical networks (model building)

Natural interpretation in terms of isoperimetry

implicit in modeling with low-dimensional spaces, manifolds, k-means, etc.

Large social/information networks are very *very* different

We examined more than 70 large social and information networks

We developed principled methods to interrogate large networks

Previous community work: on small social networks (hundreds, thousands)

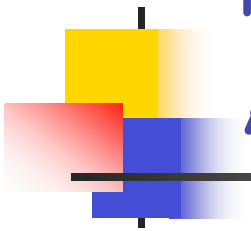
Table 1: Some of the network datasets we studied.

Probing Large Networks with Approximation Algorithms



Idea: Use approximation algorithms for NP-hard graph partitioning problems as experimental probes of network structure.

Spectral - (quadratic approx) - confuses "long paths" with "deep cuts"

Multi-commodity flow - (log(n) approx) - difficulty with expanders

SDP - (sqrt(log(n)) approx) - best in theory

Metis - (multi-resolution for mesh-like graphs) - common in practice

X+MQI - post-processing step on, e.g., Spectral of Metis

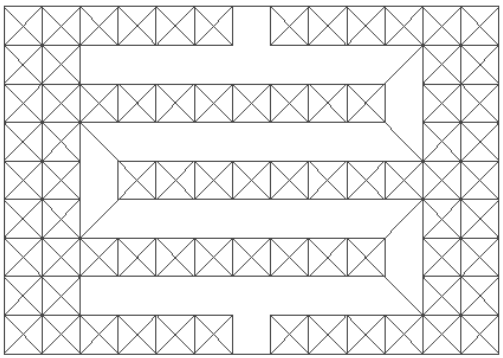
Metis+MQI - best conductance (empirically)

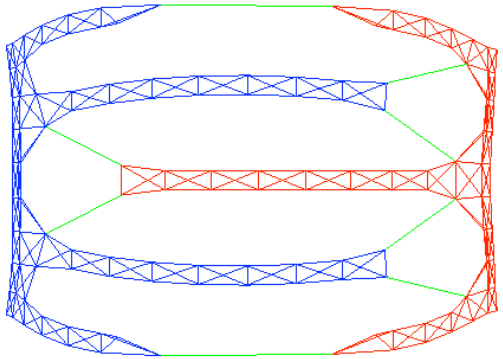
Local Spectral - connected and tighter sets (empirically, regularized communities!)

We are not interested in partitions per se, but in probing network structure.

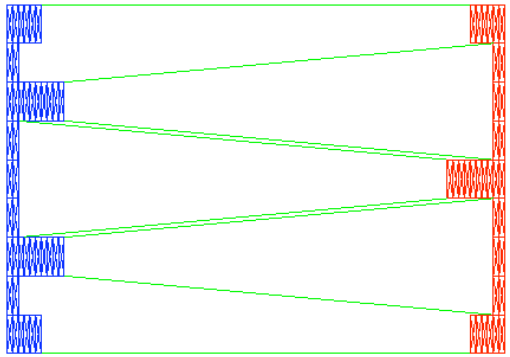
"Regularization" and spectral methods

- regularization properties: spectral embeddings stretch along directions in which the random-walk mixes slowly
  - –Resulting hyperplane cuts have "good" conductance cuts, but may not yield the optimal cuts





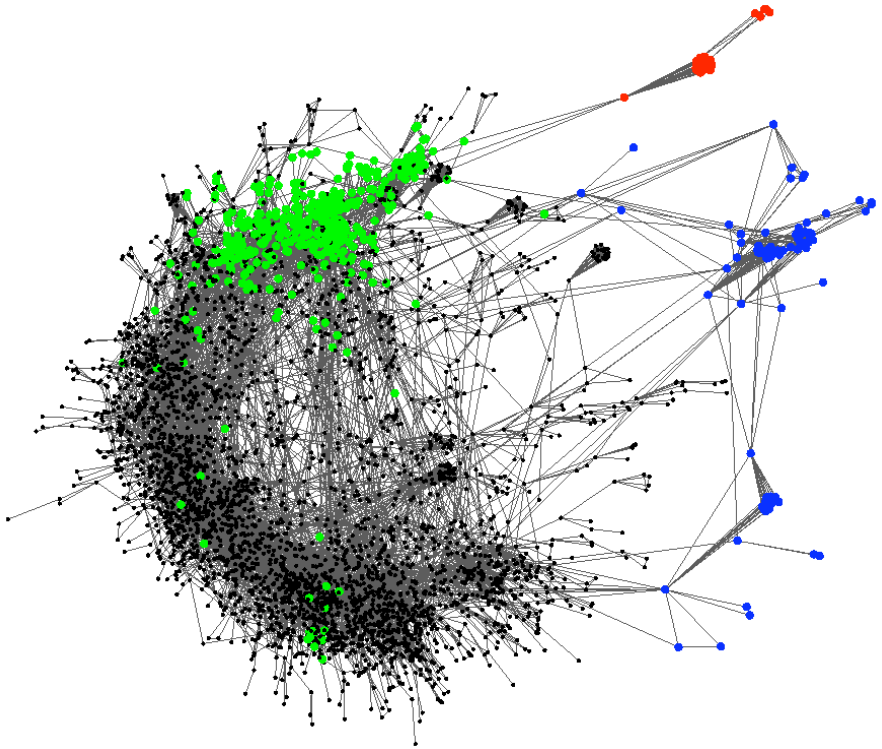
spectral embedding

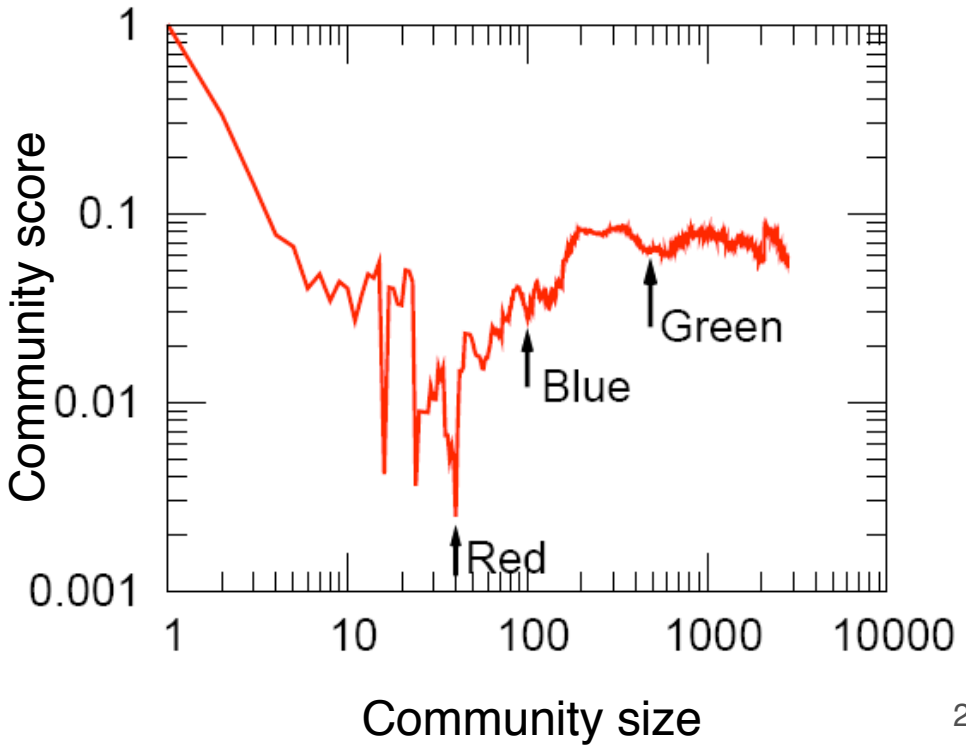


notional flow based embedding

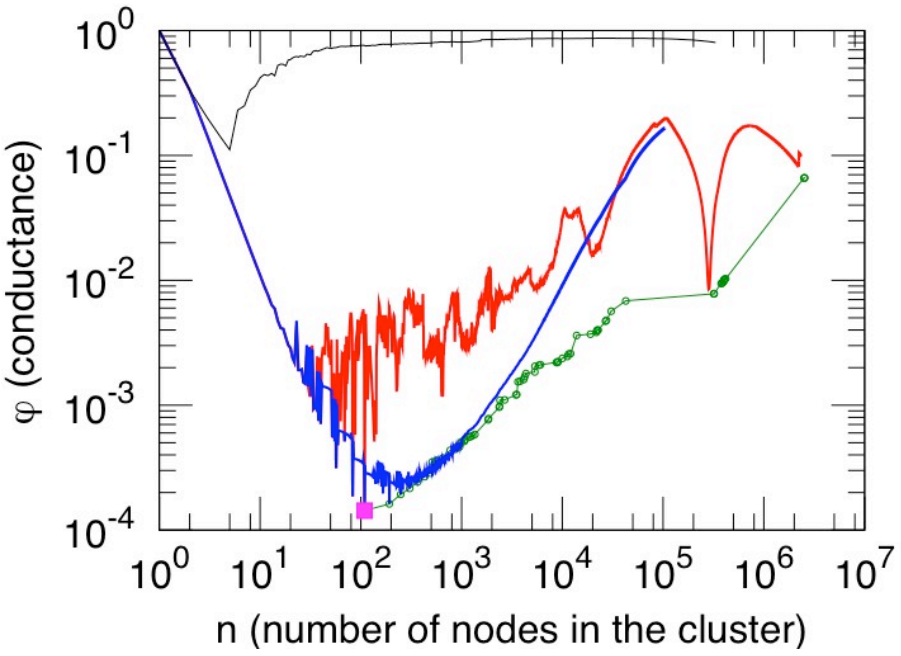
Typical example of our findings

General relativity collaboration network
(4,158 nodes, 13,422 edges)

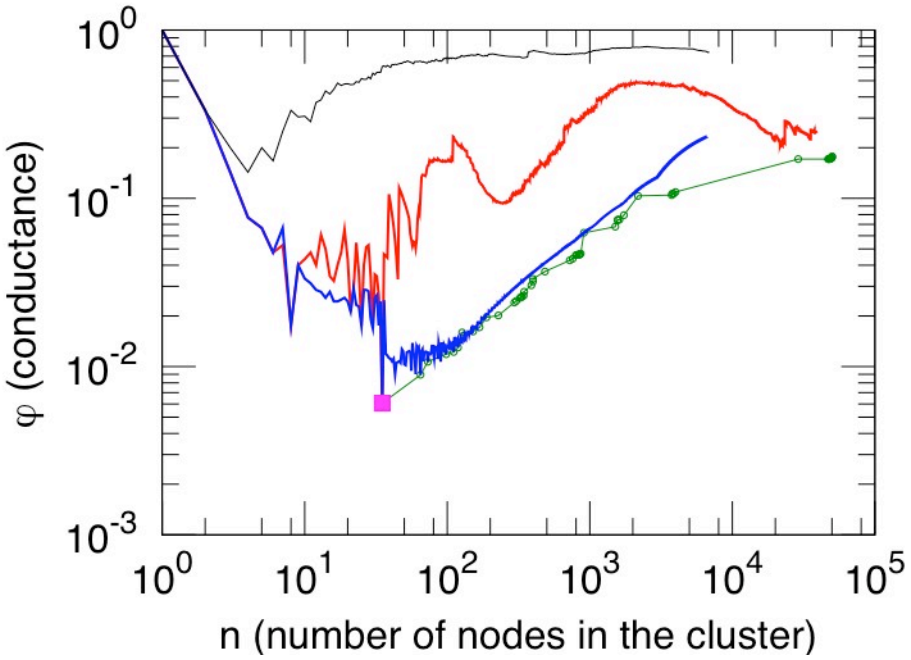




Large Social and Information Networks



LiveJournal



Epinions

Focus on the red curves (local spectral algorithm) - blue (Metis+Flow), green (Bag of whiskers), and black (randomly rewired network) for consistency and cross-validation.

More large networks

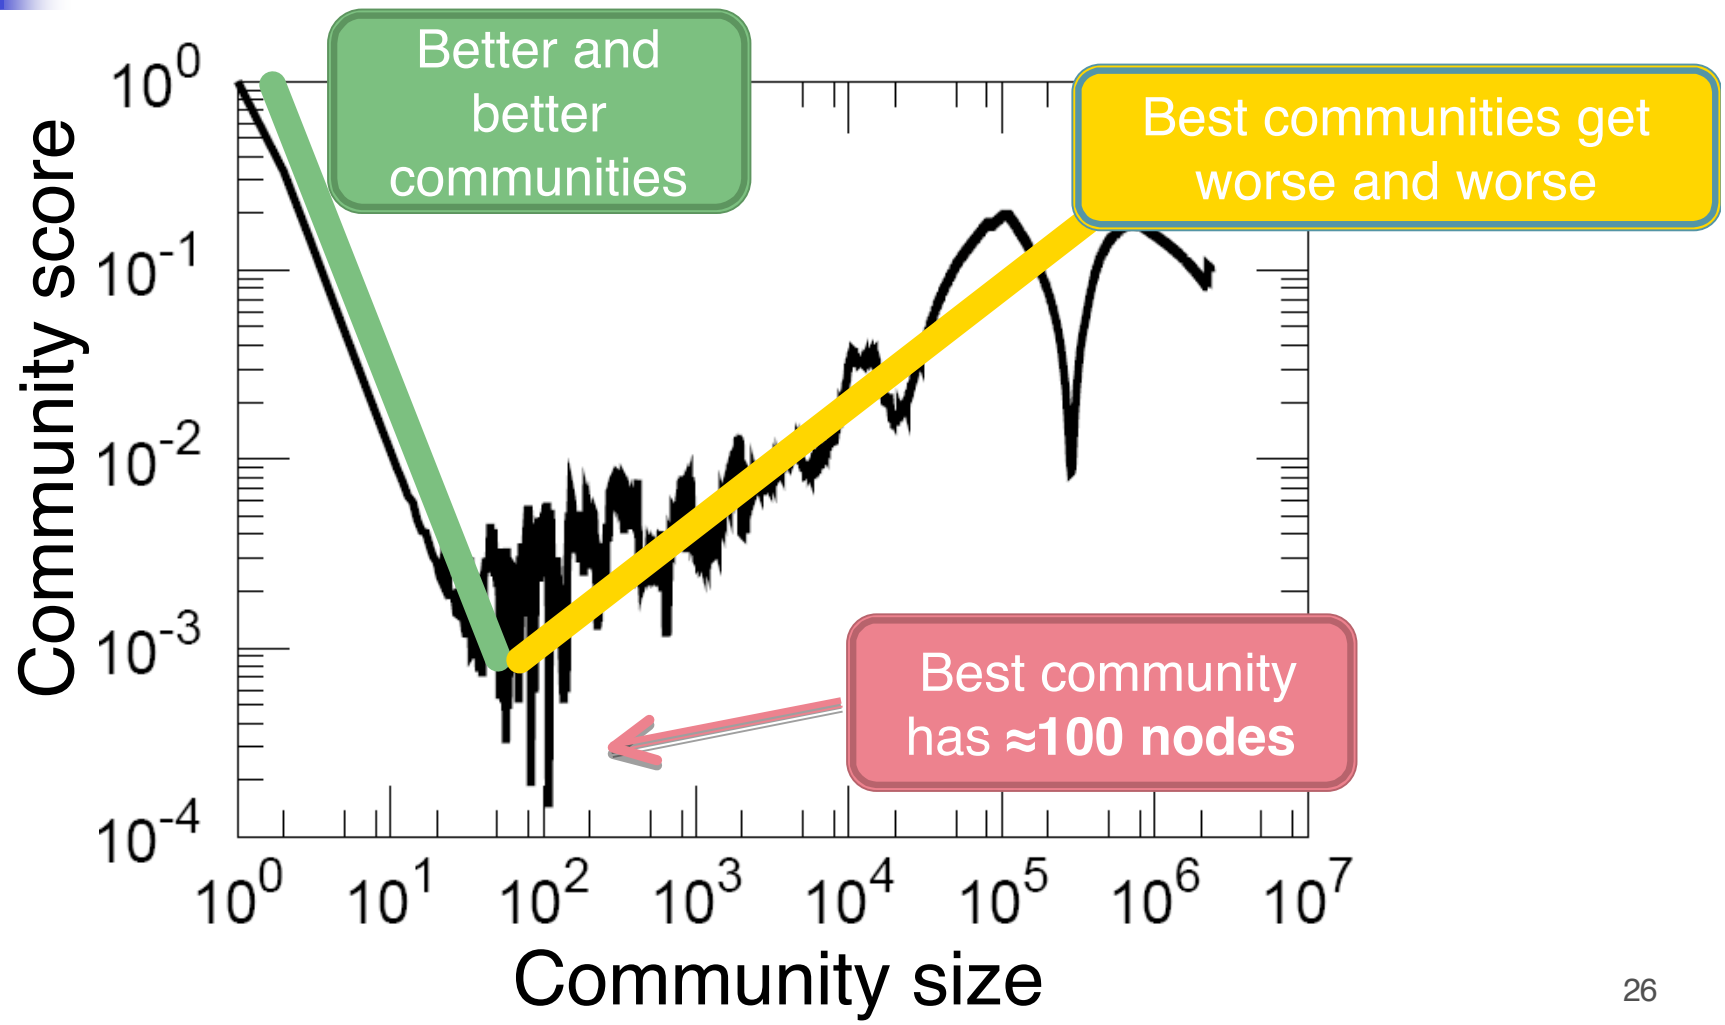
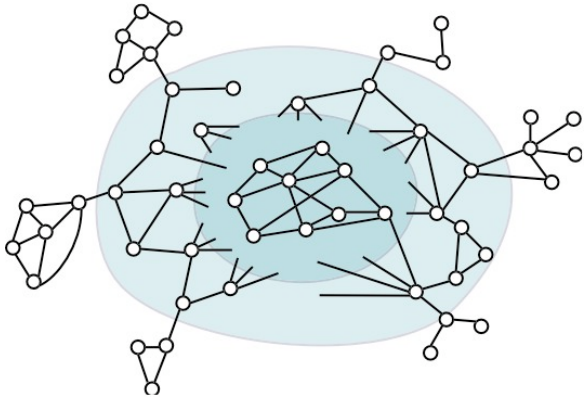
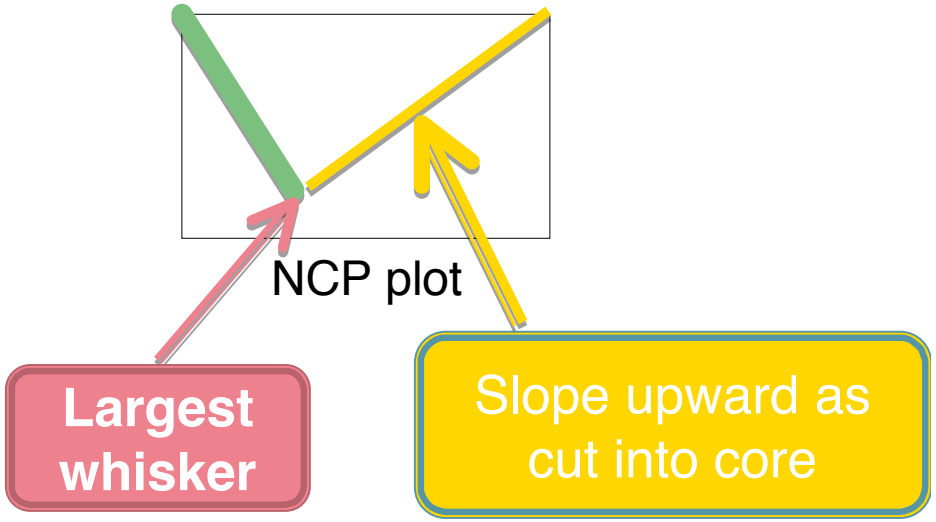
NCPP: LiveJournal (N=5M, E=43M)



"Whiskers" and the "core"

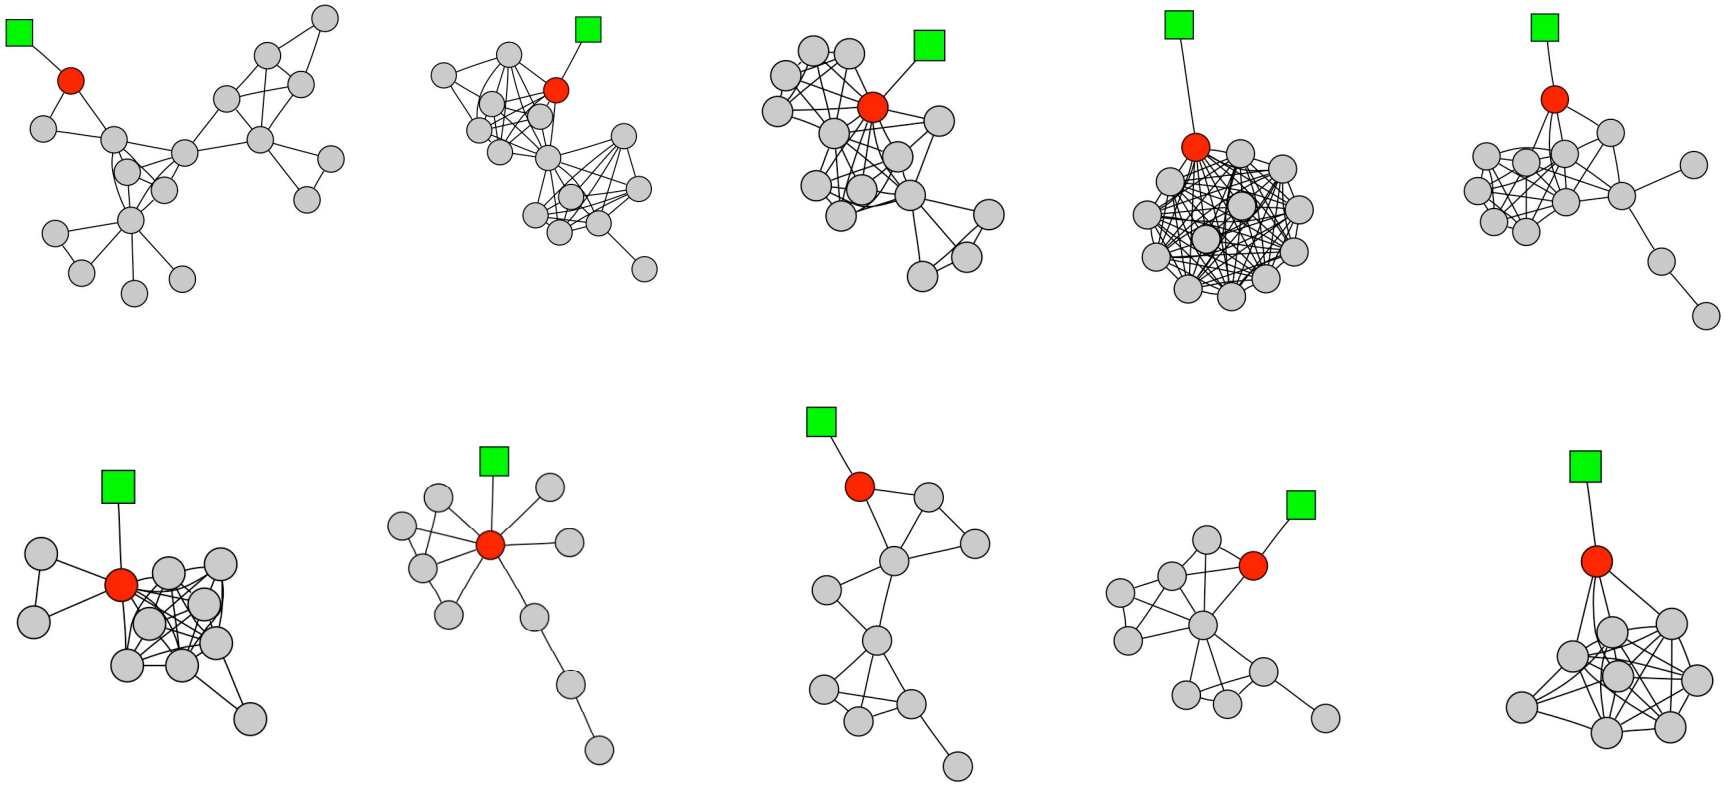
- "Whiskers"
  - maximal sub-graph detached from network by removing a single edge
  - contains 40% of nodes and 20% of edges
- "Core"
  - the rest of the graph, i.e., the 2-edge-connected core
- Global minimum of NCPP is a whisker





Examples of whiskers

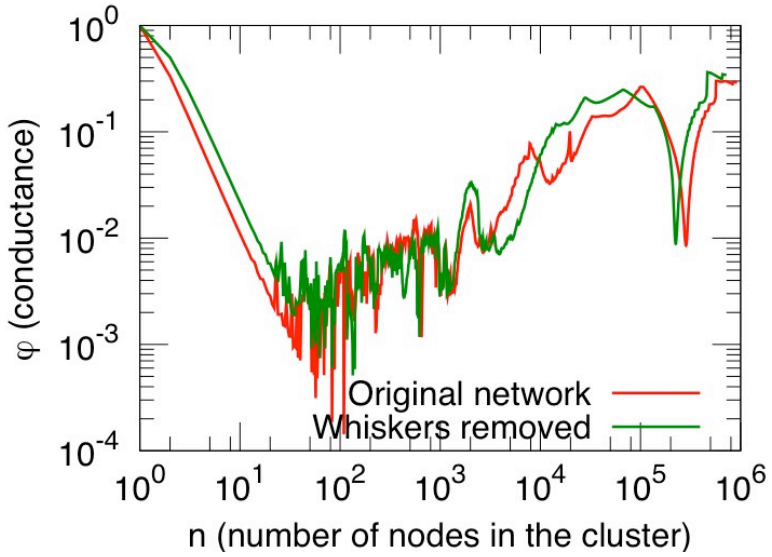
Ten largest "whiskers" from CA-cond-mat.



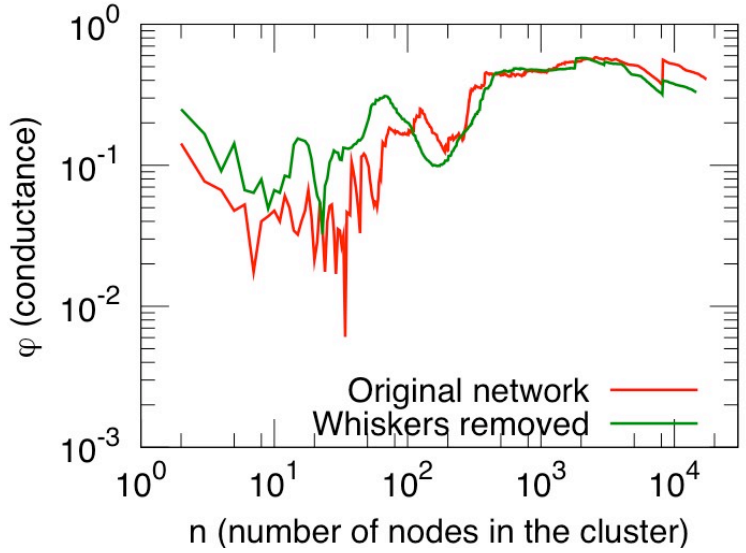
What if the "whiskers" are removed?

Then the lowest conductance sets - the "best" communities - are "2-whiskers."

(So, the "core" peels apart like an onion.)

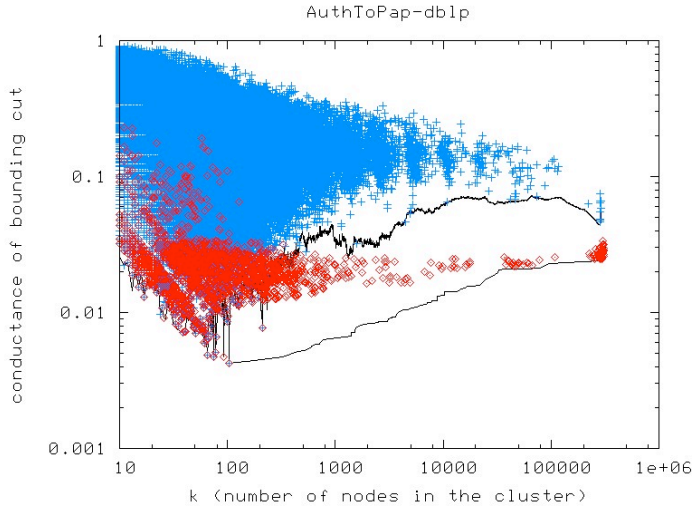


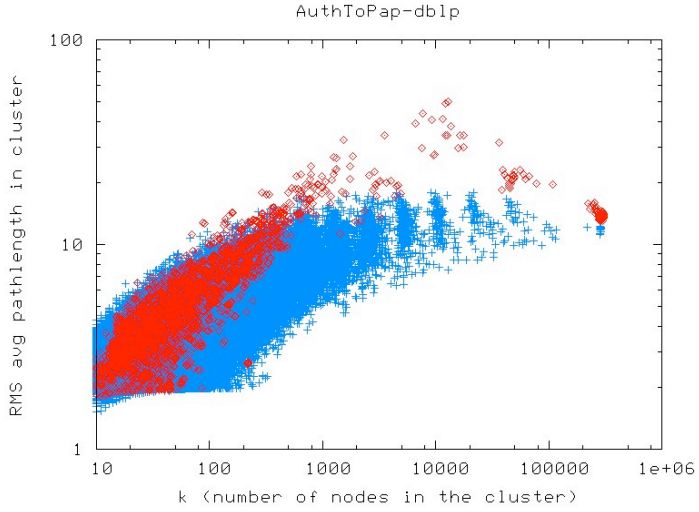
LiveJournal

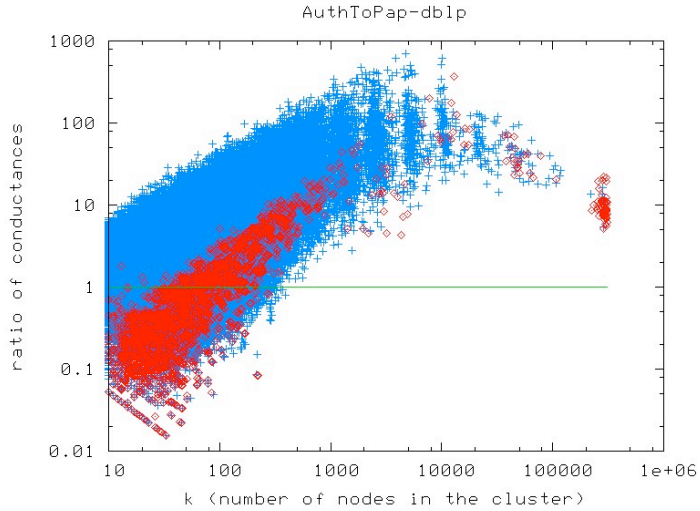


Epinions

Regularized and non-regularized communities (1 of 2)



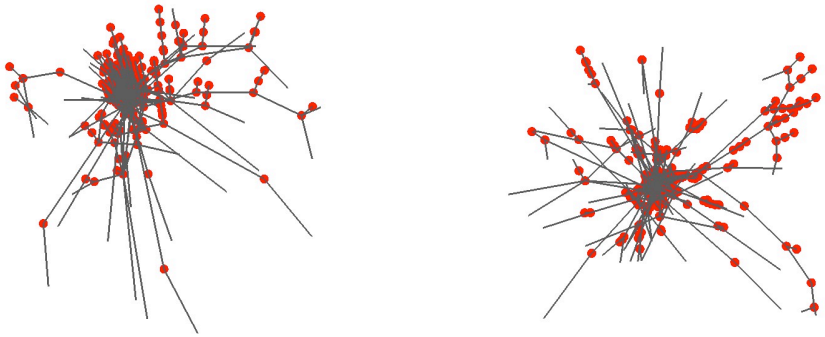




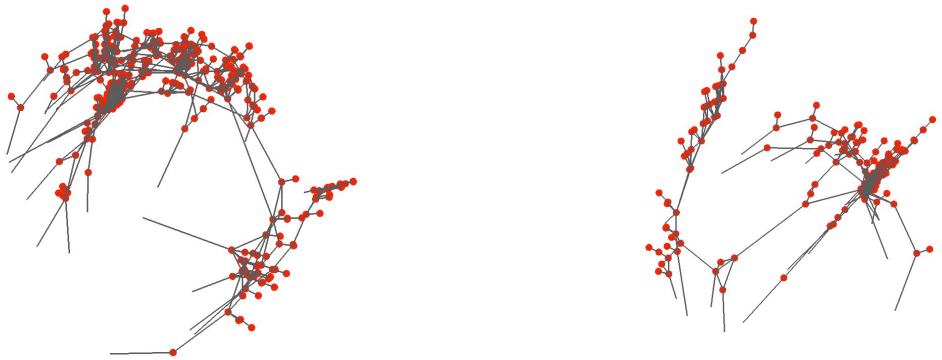
- Metis+MQI (red) gives sets with better conductance.
- Local Spectral (blue) gives tighter and more well-rounded sets.

Regularized and non-regularized communities (2 of 2)

Two ca. 500 node communities from Local Spectral Algorithm:



Two ca. 500 node communities from Metis+MQI:



Lower Bounds ...

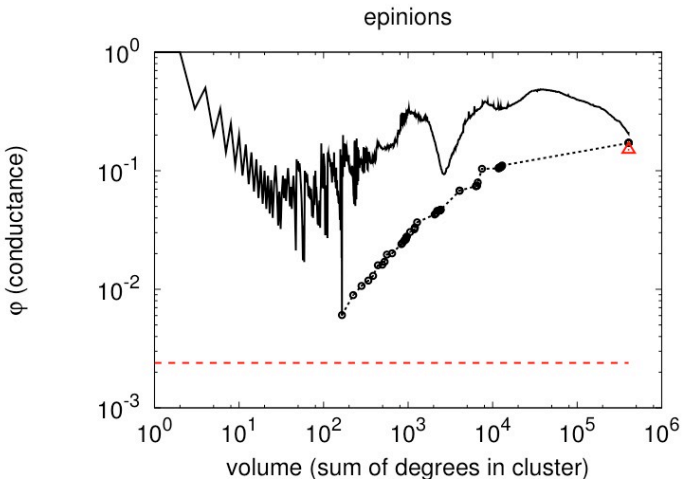
... can be computed from:

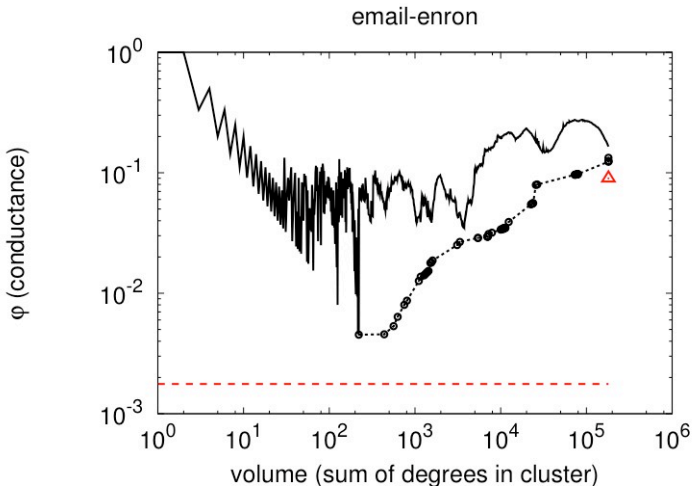
- Spectral embedding

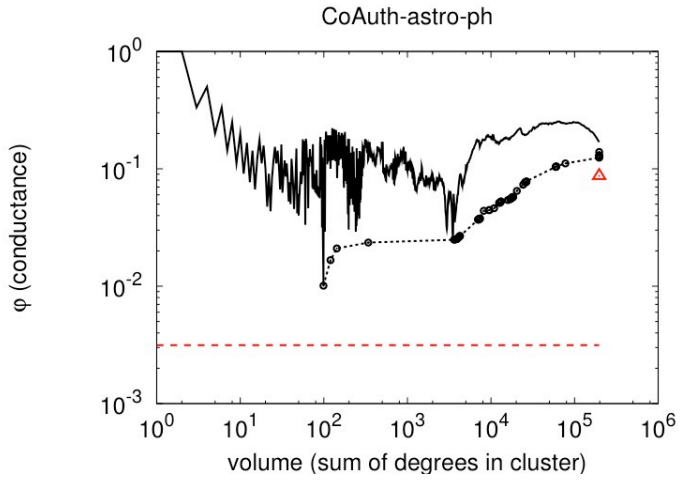
  (independent of balance)

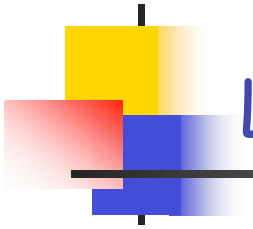
- SDP-based methods

  (for volume-balanced partitions)









Lots of Generative Models

- Preferential attachment - add edges to high-degree nodes

  (Albert and Barabasi 99, etc.)

- Copying model - add edges to neighbors of a seed node

  (Kumar et al. 00, etc.)

- Hierarchical methods - add edges based on distance in hierarchy

  (Ravasz and Barabasi 02, etc.)

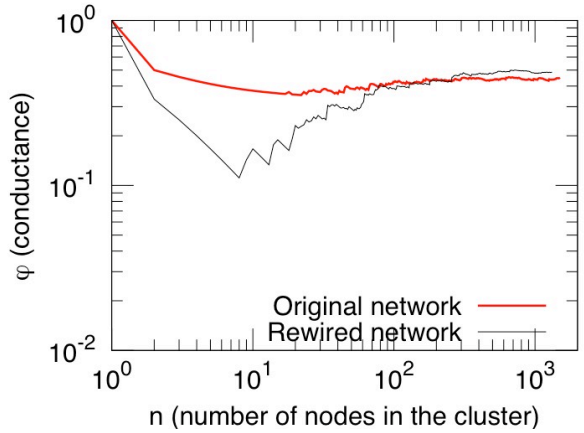
- Geometric PA and Small worlds - add edges to geometric scaffolding

  (Flaxman et al. 04; Watts and Strogatz 98; etc.)

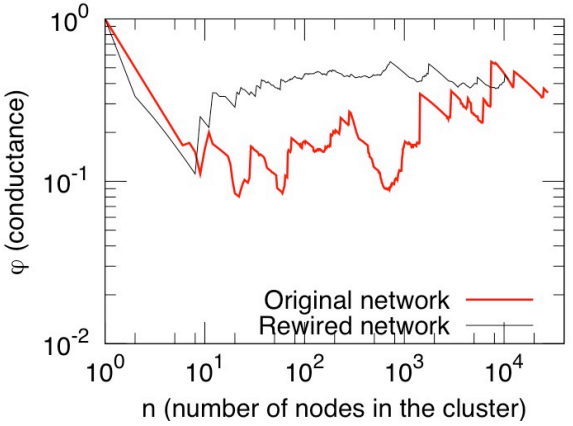
- Random/configuration models - add edges randomly

  (Molloy and Reed 98; Chung and Lu 06; etc.)

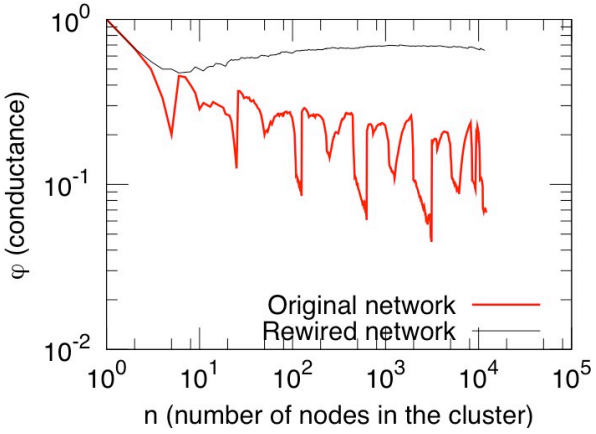
NCPP for common generative models



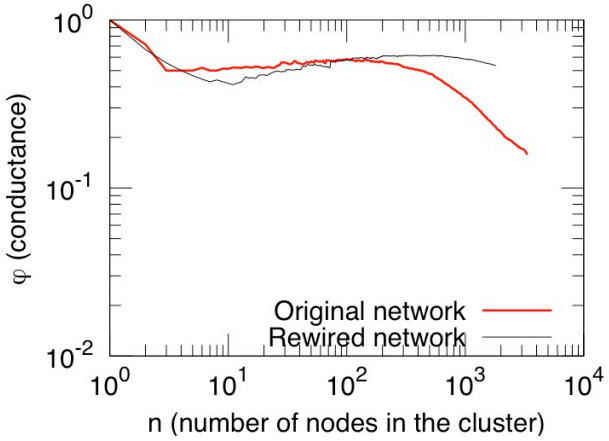
Preferential Attachment



Copying Model



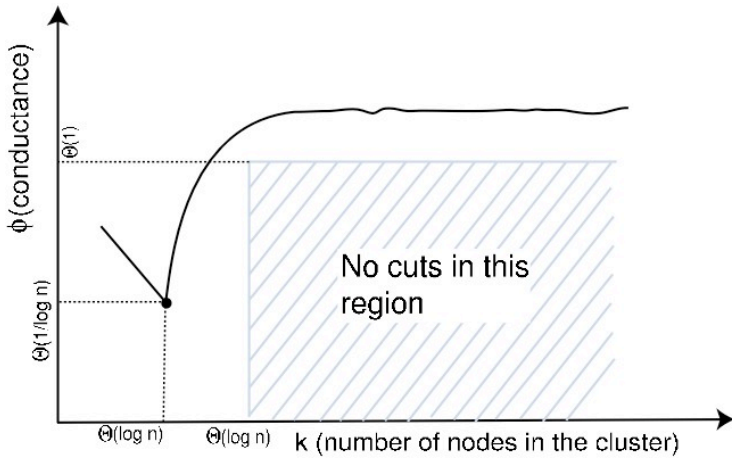
RB Hierarchical



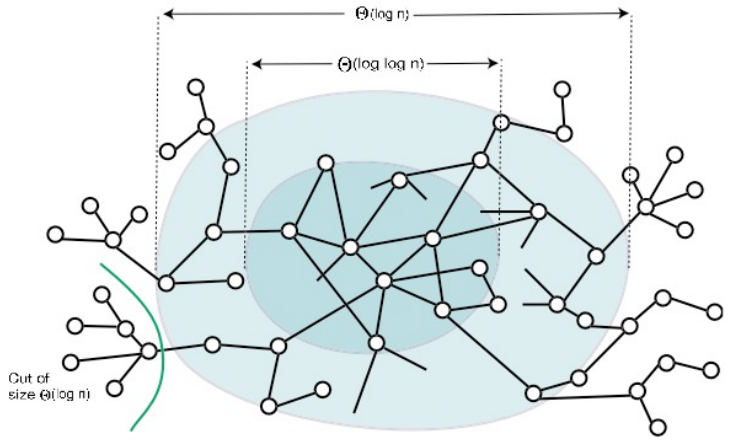
Geometric PA

A simple theorem on random graphs

Let $\mathbf{w} = (w_1, \ldots, w_n)$, where
$w_i = ci^{-1/(\beta-1)}, \quad \beta \in (2,3)$.
Connect nodes i and j w.p.
$p_{ij} = w_i w_j / \sum_k w_k$.



Power-law random graph with β ε (2,3).



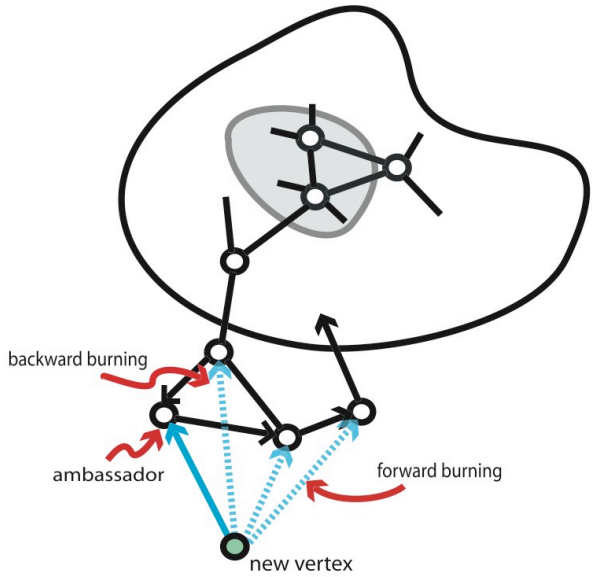
Structure of the G(w) model, with β ε (2,3).

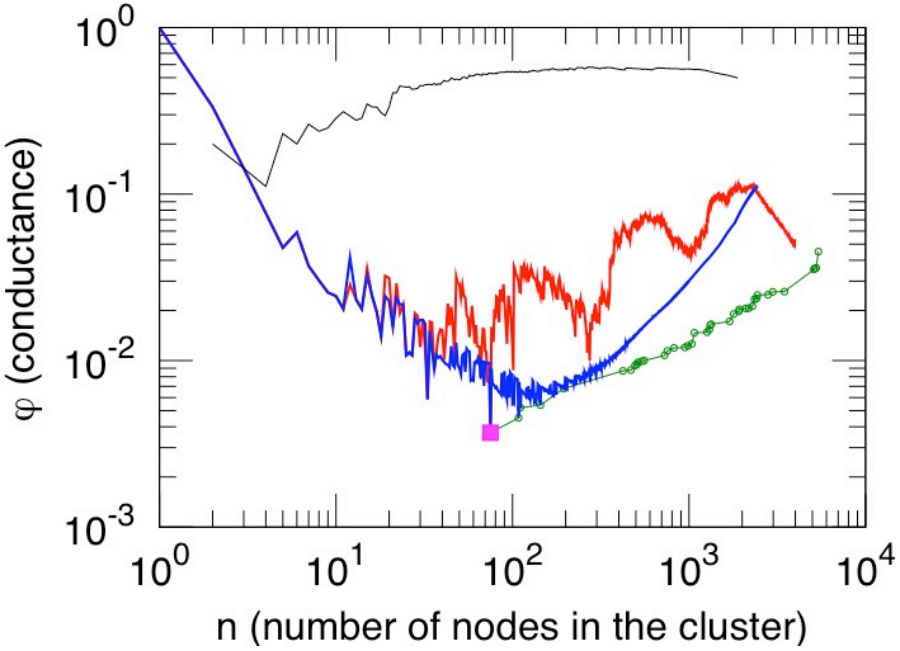
- Sparsity (coupled with randomness) is the issue, *not* heavy-tails.
- (Power laws with β ε (2,3) give us the appropriate sparsity.)

A "forest fire" model

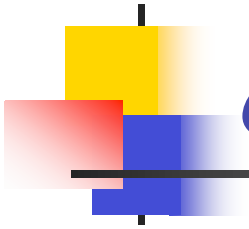
Model of: Leskovec, Kleinberg, and Faloutsos 2005

At each time step, iteratively add edges with a "forest fire" burning mechanism.





Also get "densification" and "shrinking diameters" of real graphs with these parameters (Leskovec et al. 05).

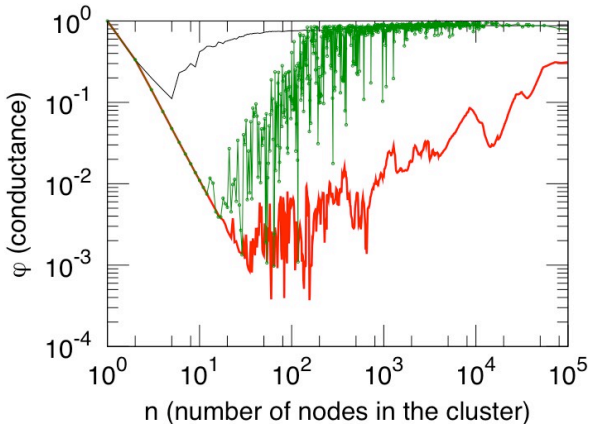


Comparison with "Ground truth" (1 of 2)

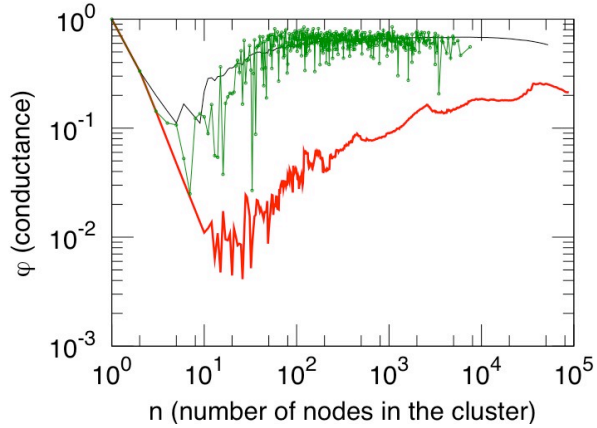
Networks with "ground truth" communities:

- LiveJournal12:
  - users create and explicitly join on-line groups
- CA-DBLP:
  - publication venues can be viewed as communities
- AmazonAllProd:
  - each item belongs to one or more hierarchically organized categories, as defined by Amazon
- AtM-IMDB:
  - countries of production and languages may be viewed as communities (thus every movie belongs to exactly one community and actors belongs to all communities to which movies in which they appeared belong)

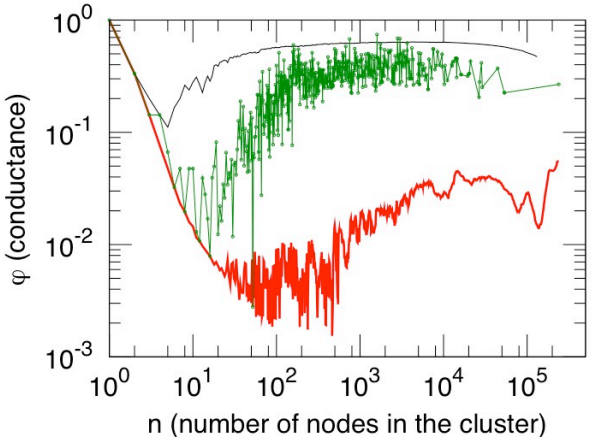
Comparison with "Ground truth" (2 of 2)



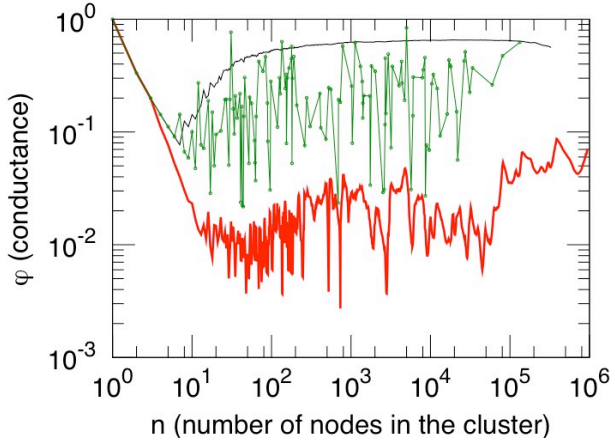
LiveJournal



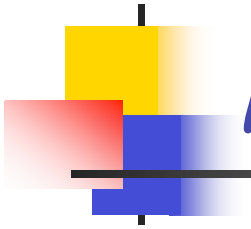
CA-DBLP



AmazonAllProd



AtM-IMDB



Miscellaneous thoughts …

Sociological work on community size (Dunbar and Allen)

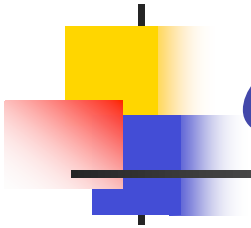
- 150 individuals is maximum community size
- Military companies, on-line communities, divisions of corporations all ≤ 150

Common bond vs. common identity theory

- Common bond - people are attached to individual community members
- Common identity - people are attached to the group as a whole

What edges "mean" and community identification

- social networks - reasons an individual adds a link to a friend very diverse
- citation networks - links are more "expensive" and semantically uniform.



Conclusions

Approximation algorithms as experimental probes!

- Hard-to-cut onion-like core with more structure than random
- Small well-isolated communities gradually blend into the core

Community structure in large networks is qualitatively different!

- Agree with previous results on small networks
- Agree with sociological interpretation (Dunbar's 150 and bond vs. identity)!

Common generative models don't capture community phenomenon!

- Graph locality - important for realistic network generation
- Local regularization - important due to sparsity
