Why adjust?

The unadjusted difference in means is an unbiased estimator of the average treatment effect.

So why do researchers use regression adjustment?

- **Fishing**
- **Precision improvement**
(Fisher 1932; Cochran 1957; Cox & McCullagh 1982)

Assumptions:

- Regression model is correct
- Fixed covariate list (no fishing)
- $K \ll N$
- Outcome correlated with at least one covariate

Adjustment tends to reduce the variance of the estimated treatment effect.

(This is the standard rationale.)

bias

Possible directions

Freedman finds that under Neyman's model:

- 1 Adjustment can actually worsen asymptotic precision.
- 2 The conventional OLS standard error estimator is inconsistent.
- 3 The adjusted estimator has a finite-sample bias of order $1/N$.

Freedman's conclusions

Freedman finds that under Neyman's model:

- ① Adjustment can actually worsen asymptotic precision.
- ② The conventional OLS standard error estimator is inconsistent.
- ③ The adjusted estimator has a finite-sample bias of order $1/N$.

“The reason for the breakdown is not hard to find:
randomization does not justify the assumptions
behind the OLS model.”

Consistency of regression estimators

Claim

Under simple random sampling,
 \widehat{Y}_{OLS} is a consistent estimator of \bar{Y}_{pop} ,
even if the regression model is false.

Sketch of Proof

$$\widehat{Y}_{OLS} - \bar{Y}_{sample} = \widehat{\beta}_{OLS} \cdot (\bar{X}_{pop} - \bar{X}_{sample})$$

Under suitable regularity conditions:

- 1 $(\bar{X}_{pop} - \bar{X}_{sample}) \xrightarrow{P} 0$.
- 2 $\widehat{\beta}_{OLS}$ converges to a finite limit.
- 3 Therefore, $(\widehat{Y}_{OLS} - \bar{Y}_{sample}) \xrightarrow{P} 0$.
- 4 \bar{Y}_{sample} is consistent.
- 5 Therefore, \widehat{Y}_{OLS} is consistent.

Claim

Under simple random sampling,
OLS adjustment of the estimated mean
cannot hurt asymptotic precision,
even if the regression model is false.

Sketch of Proof (adapted from Cochran 1977)

First, imagine using a “fixed-slope regression estimator”:

$$\widehat{Y}_{fixedslope} \equiv \bar{Y}_{sample} + b \cdot (\bar{X}_{pop} - \bar{X}_{sample})$$

where b is a constant.

② Estimate $\bar{Y}_{0,pop}$

- Regress Y_i on X_i in control group $\rightarrow \hat{\beta}_{control}$
- $\hat{Y}_{0,OLS} = \bar{Y}_{control} + \hat{\beta}_{control} \cdot (\bar{X}_{pop} - \bar{X}_{control})$

③ Take the difference

$$\widehat{ATE}_{ANCOVA II} = \hat{Y}_{1,OLS} - \hat{Y}_{0,OLS}$$

- Equivalent to regressing Y_i on T_i , X_i , and $T_i \cdot (X_i - \bar{X}_{pop})$
- Similar to a well-known nonexperimental method

Possible
directions

For simplicity, assume a single covariate X_i .
Results generalize to multiple covariates.

Condition 1

Y_{1i} , Y_{0i} , and X_i have bounded fourth moments.
For example, there exists $L < \infty$ such that

$$\frac{1}{N} \sum_{i=1}^N X_i^4 < L \quad \text{for } N = 1, 2, \dots$$

Freedman's regularity conditions

Condition 2

The population means, variances, and covariances of Y_{1i} , Y_{0i} , and X_i converge to finite limits.
The limits of the variances are positive.

- But the result sheds light on Freedman's warning that adjustment can hurt asymptotic precision.

The essential problem is omission of
treatment \times covariate interactions,
not the linear model.

Freedman's critique conflates two independent choices:

- To adjust, or not to adjust?
- To assume homoskedasticity, or not?

- MSE (or another loss function), not bias
- Adjustment may reduce conditional bias

The leading term in the bias reflects omitted squared covariates (Cochran 1942, 1977)

With a saturated model, ANCOVA II is unbiased

- Equivalent to post-stratification (subclassification and weighting)
- Miratrix (2011) gives exact variance

Possible directions for further research

Permutation inference with covariate adjustment (Rosenbaum 2002)

Reexamining Freedman's complaints

Asymptotic
precision loss

Inconsistent SE

Finite-sample
bias

Possible directions

Possible directions for further research

Permutation inference with covariate adjustment (Rosenbaum 2002)

- Some see this as a remedy for Freedman's complaints (2011)
- Actually doesn't address any of Freedman's issues
- Assumes constant treatment effect and thus homoskedasticity

- Actually doesn't address any of Freedman's issues
- Assumes constant treatment effect and thus homoskedasticity
- Janssen (1997): Look at permutation distribution of unequal-variance t -statistic

Cluster-randomized experiments

- Multilevel models allow between- and within-cluster slopes to differ
- Gains from adjustment may be especially high (Raudenbush 1997)
- But the number of clusters may often be too small to rely on asymptotics

I would like to thank:

- Jas Sekhon for very valuable advice and encouragement
- Peter Aronow, Gus Baker, Erin Hartman, Danny Hidalgo, Alex Mayer, Luke Miratrix, Cyrus Samii, Dylan Small, and seminar participants at Berkeley for helpful comments
- David Freedman for his generous advice and help earlier in my education

All shortcomings of this work are solely my responsibility.

Outline

OLS adjustment and Freedman's critique

- The practice of adjustment
- Why adjust?
- Freedman's critique

Toward an agnostic view

- Overview of this paper
- Lessons from survey sampling

Reexamining Freedman's complaints

- Asymptotic precision loss
- Inconsistent SE
- Finite-sample bias

Possible directions
